NEUTRINO EXPERIMENT

## What is an arapuca?

- The word comes from the Guaraní language and means "bird buster", referring to a classical trap build by the Brazilian natives to catch small animals.
- Despite its rudimentary look, it is a clever and efficient device.
- The basic principle is: "bird goes in and can't get out" (as all traps should do)

## What is the ARAPUCA?

- The ARAPUCA is a photon detection device which works by enhancing a commercially available silicon photomultiplier (SiPM).
- In this case, "enhancing" means increasing the collection area and re-tuning its wavelength sensibility.
- The basic principle is: "photon goes in and can't get out" (and that's the analogy).

"Let there be Light Traps" by Lauren Biron

Symmetry Magazine, 2019

[www.symmetrymagazine.org/article/arapuca-let-there-be-light-traps](http://www.symmetrymagazine.org/article/arapuca-let-there-be-light-traps)

## The ARAPUCA Family of devices

- It comes in different forms, but always with the same characteristic "mosaic" look, due a limitation in the filters manufacturing.
- Cover area goes from tens of  $\text{cm}^2$  up to  $\text{m}^2$ .
- These are actually X-ARAPUCAs, which are the second generation (I will explain the difference in a moment).

## How does it work?

## X-ARAPUCA design

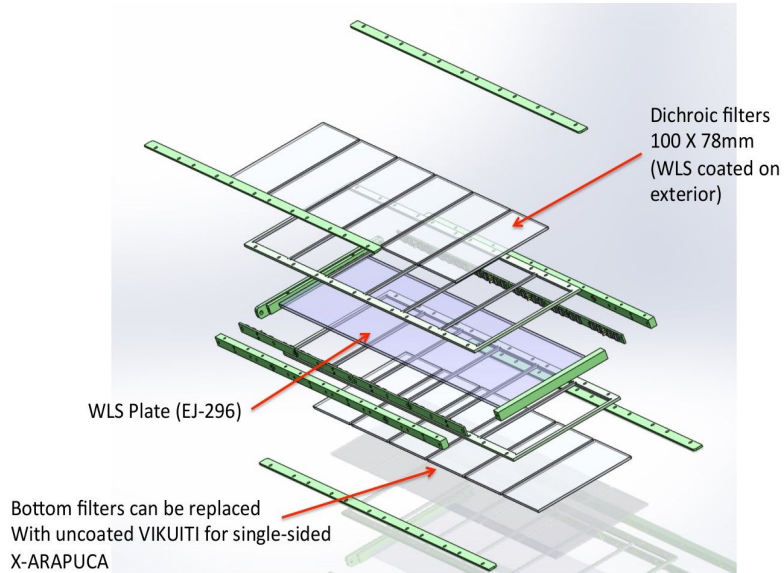

## Dualcell Model (SBND)

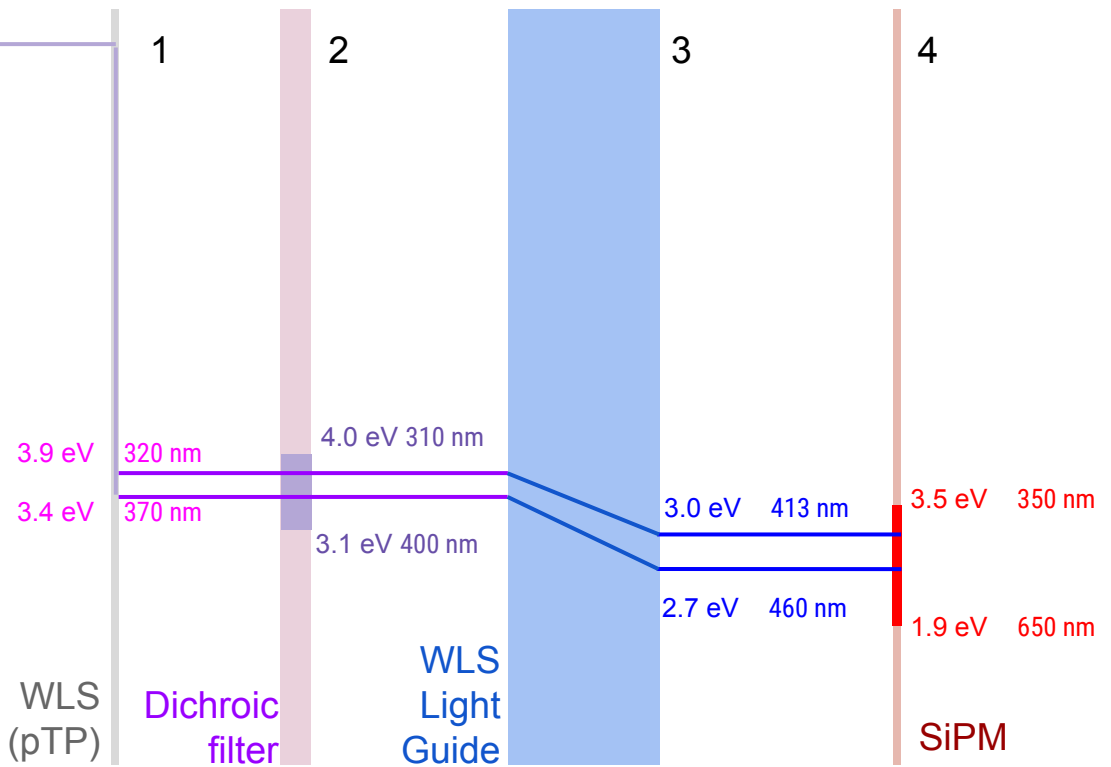

## Supercell Model (DUNE)

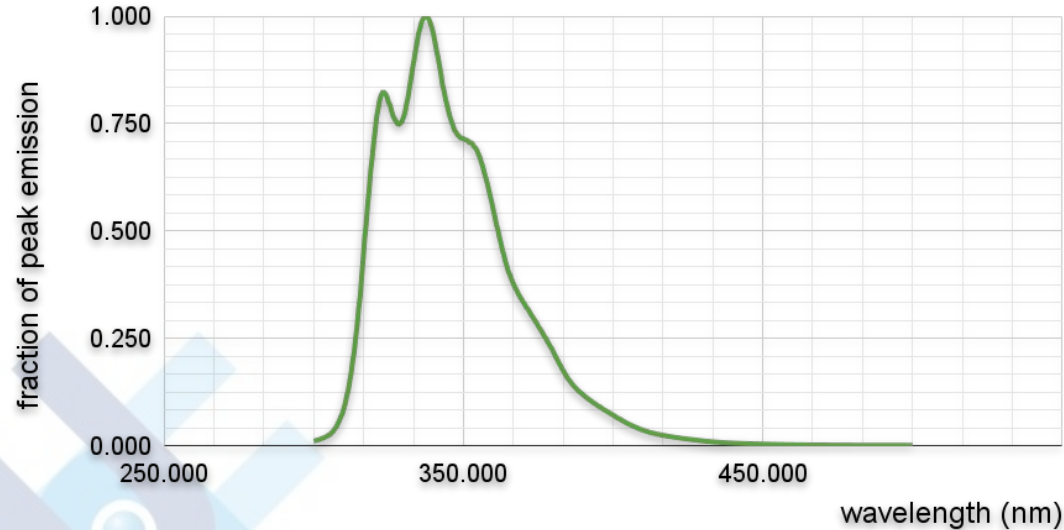

## Energy Diagram X-ARAPUCA

1. Wavelength Shifter 1
2. Dichroic Filter (band-pass)
3. Wavelength Shifter 2
4. Silicon Photomultiplier

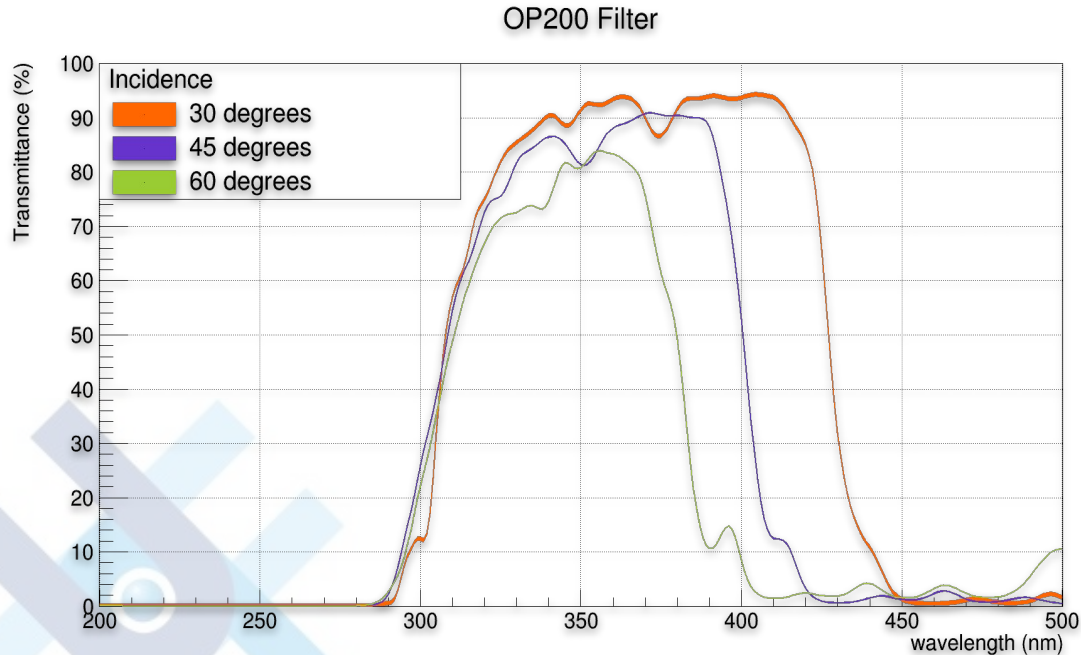

## pTerphenil (pTP) - wavelength shifter 1

pTerphenyl (PTP) emission

- Converts 128 nm light from LAr to its spectrum ~320 to 370 nm.
- Layer is designed to be ~100% absorbent.
- Emission is isotropic, so only 50% of incoming light has a chance of going into the trap.

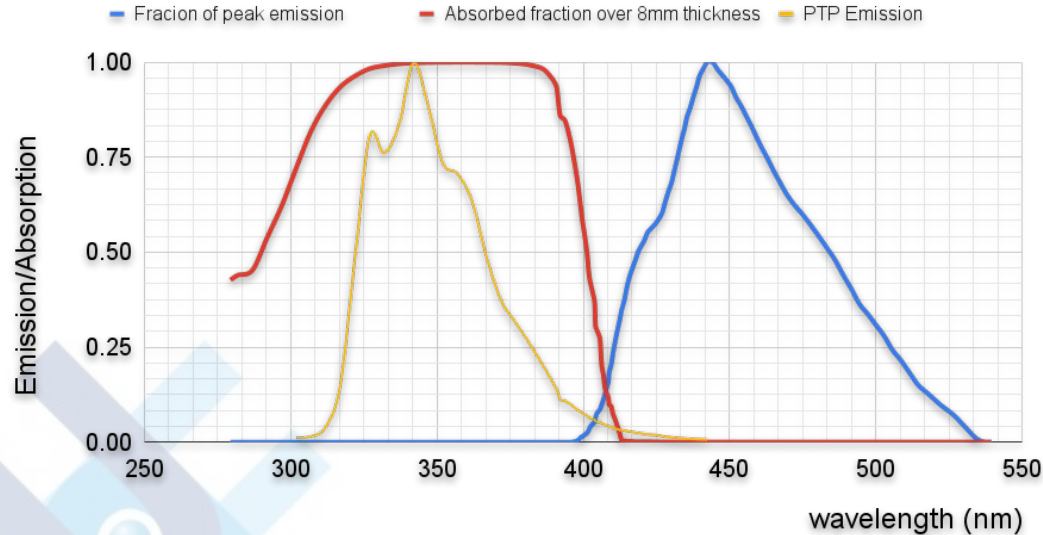

## Dichroic filter - optical band-pass

- Interference layers deposited over a glass substrate.
- Designed to allow the pTP spectrum to pass with 45° incidence.
- Average transmission over 80% for the pTP spectrum.

## EJ286 - wavelength shifter 2

EJ286

- Light-guide doped with commercial shifter (ELJEN)
- Concentration of dopant enough to make it 100% absorbent over the pTP spectrum.
- Emission is isotropic. Part of the converted light is trapped inside the guide, leading to the SiPM (see next slide).

## Conversion + guiding effect

- Due to the combination of refraction indices,  $\sim 57\%$  of the converted light is guided.
- The remaining 43% is trapped between the filter and the Vikuiti reflector at the bottom.

## Hamamatsu S13360 (SiPM) - Silicon Photomultiplier

Hamamatsu S13360

- Most sensible to the EJ286 emission spectrum.
- Can be operated at overvoltages, driving the average efficiency to ~50%.
- Compatible with cryogenic environments.

## X-ARAPUCA Numbers

- Maximum theoretical efficiency:  $50\% \times 80\% \times 57\% \times 50\% < 12\%$
- Real efficiency measured to be between **2 and 3%**
- SiPM area =  $48 \times 6\text{mm}^2 = 288\text{ mm}^2$  | Collection area =  $6 \times 7800\text{ mm}^2 = 46800\text{ mm}^2 \rightarrow$  increase of **162 times**
- Even if we multiply by the efficiencies (we shouldn't but...)  $288 \times 50\% = 144\text{ mm}^2$ , while  $46800 \times 2\% = 936\text{ mm}^2$

a gain of 6.5 times of effective area

## DUNE's Detectors

## DUNE's Photon Detection System

## DUNE's Photon Detection System

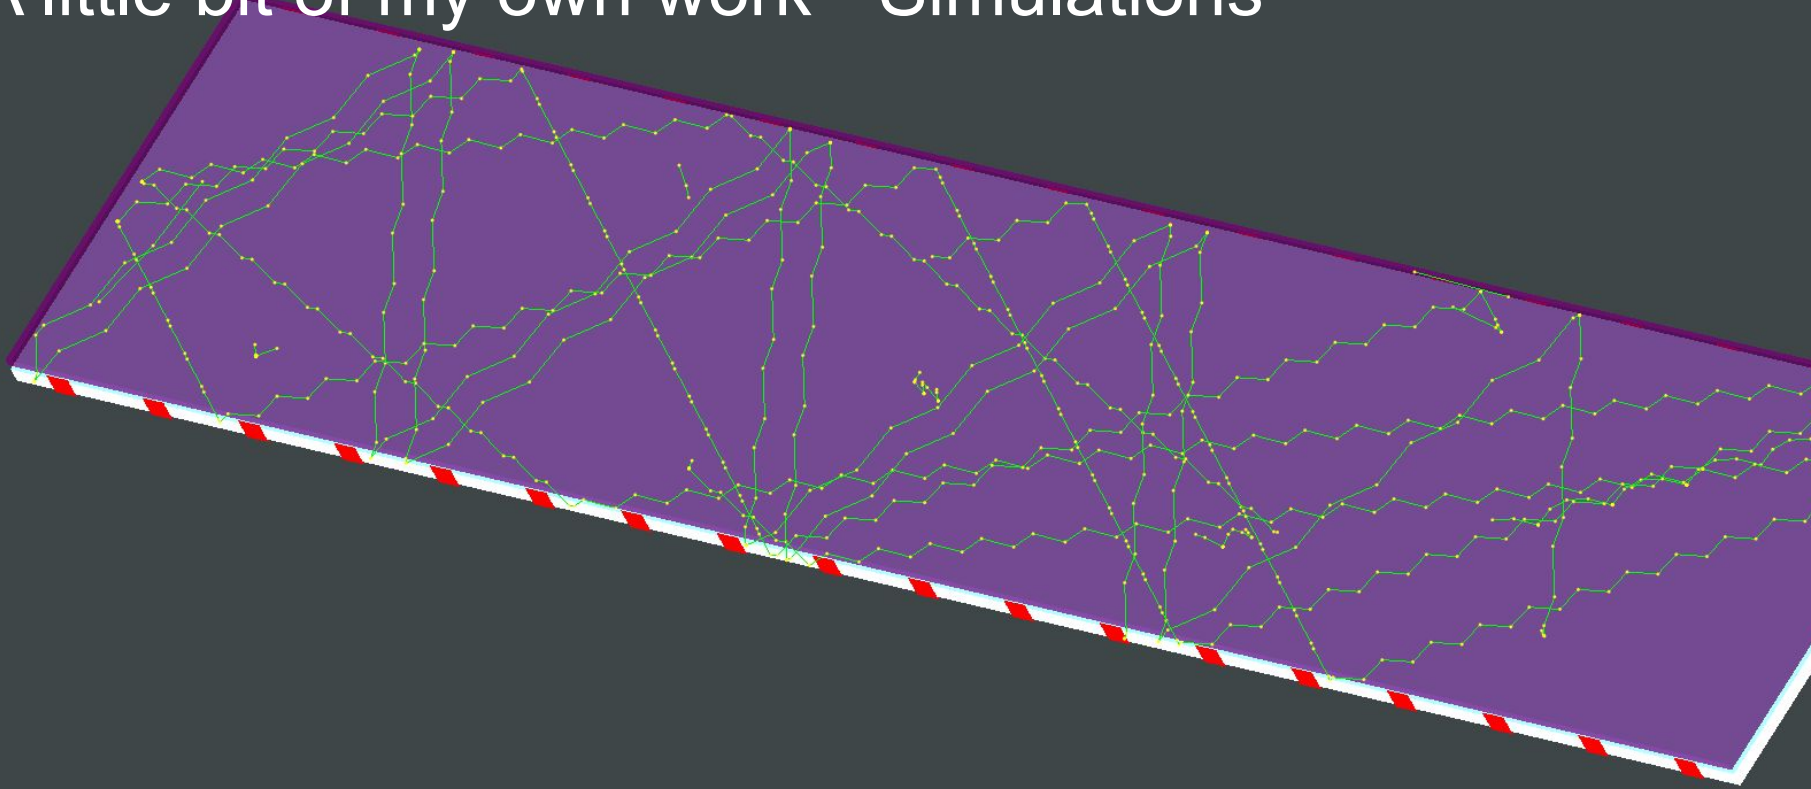

- 1500 Modules
- 6000 Supercells
- 36000 filters
- 288000 SiPMs

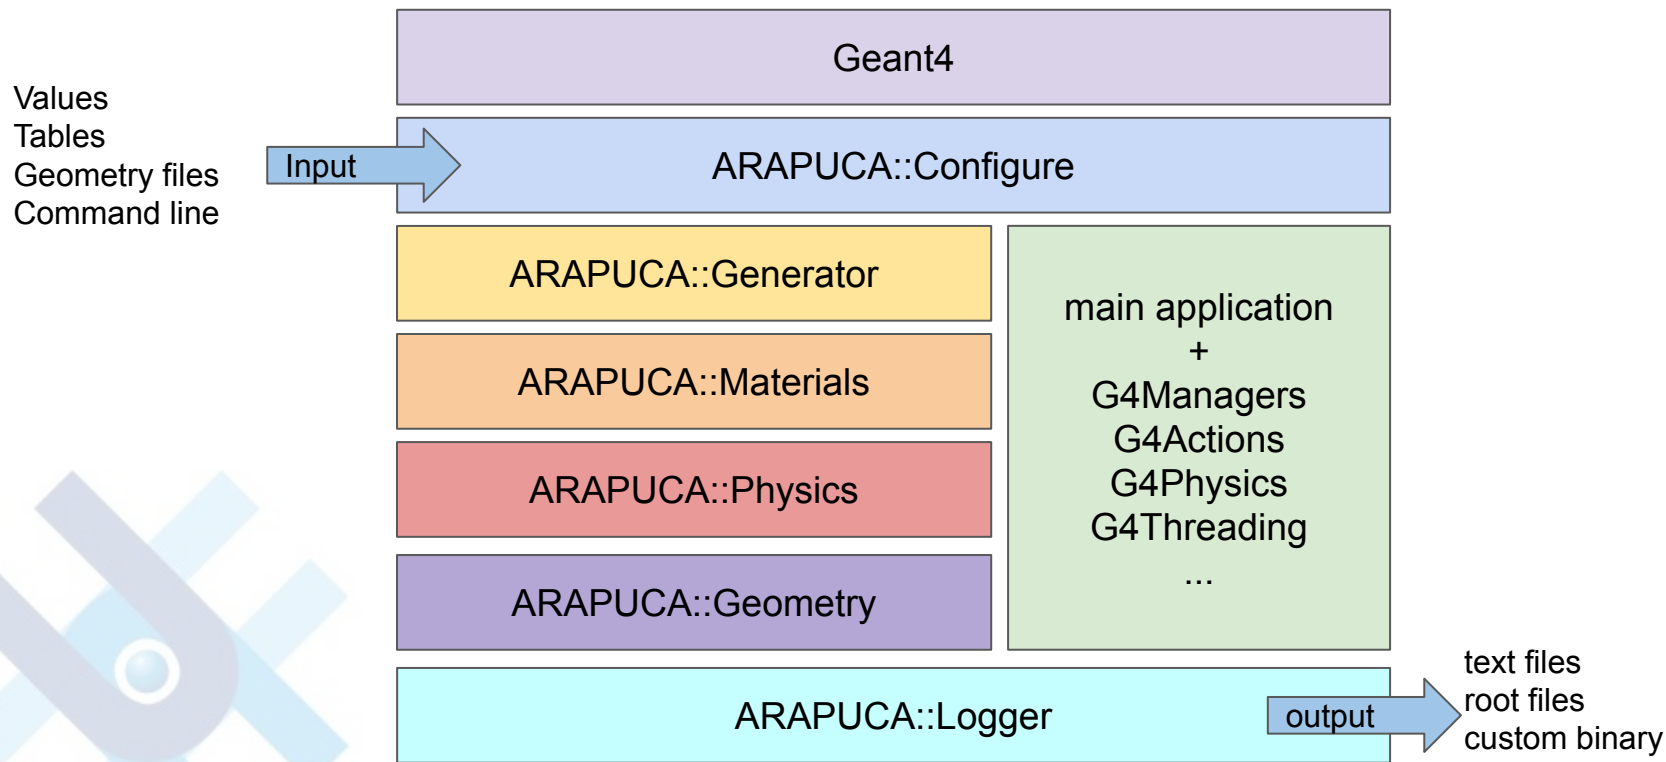

# A little bit of my own work - Simulations

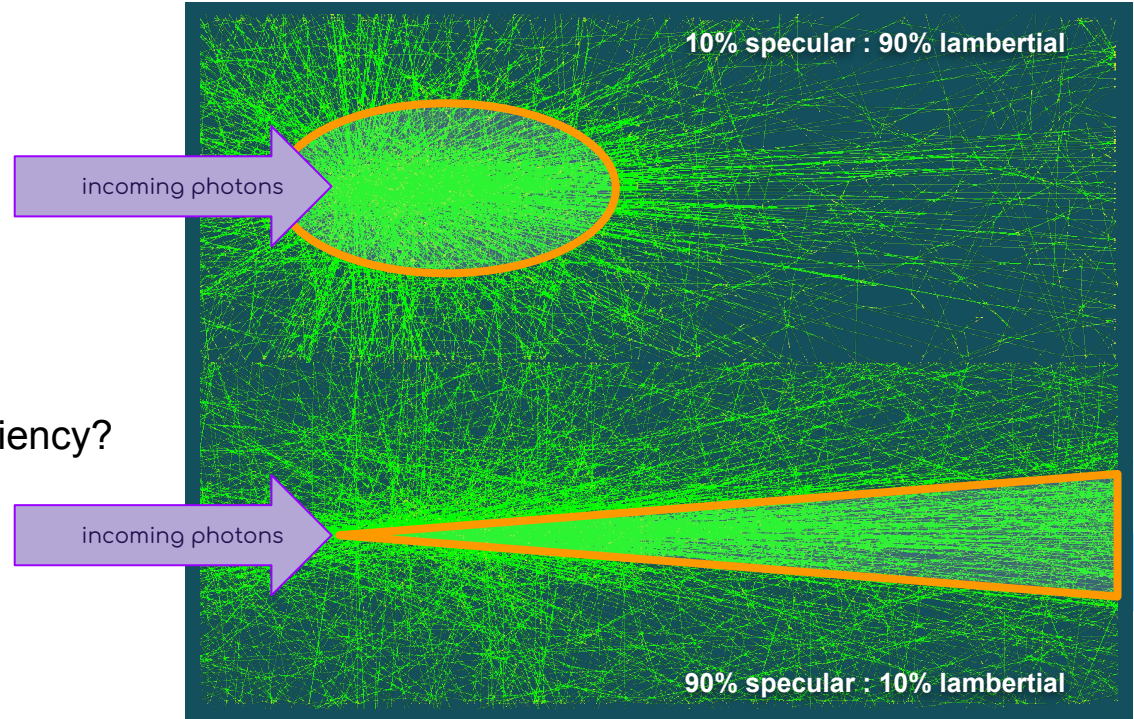

# Software Architecture

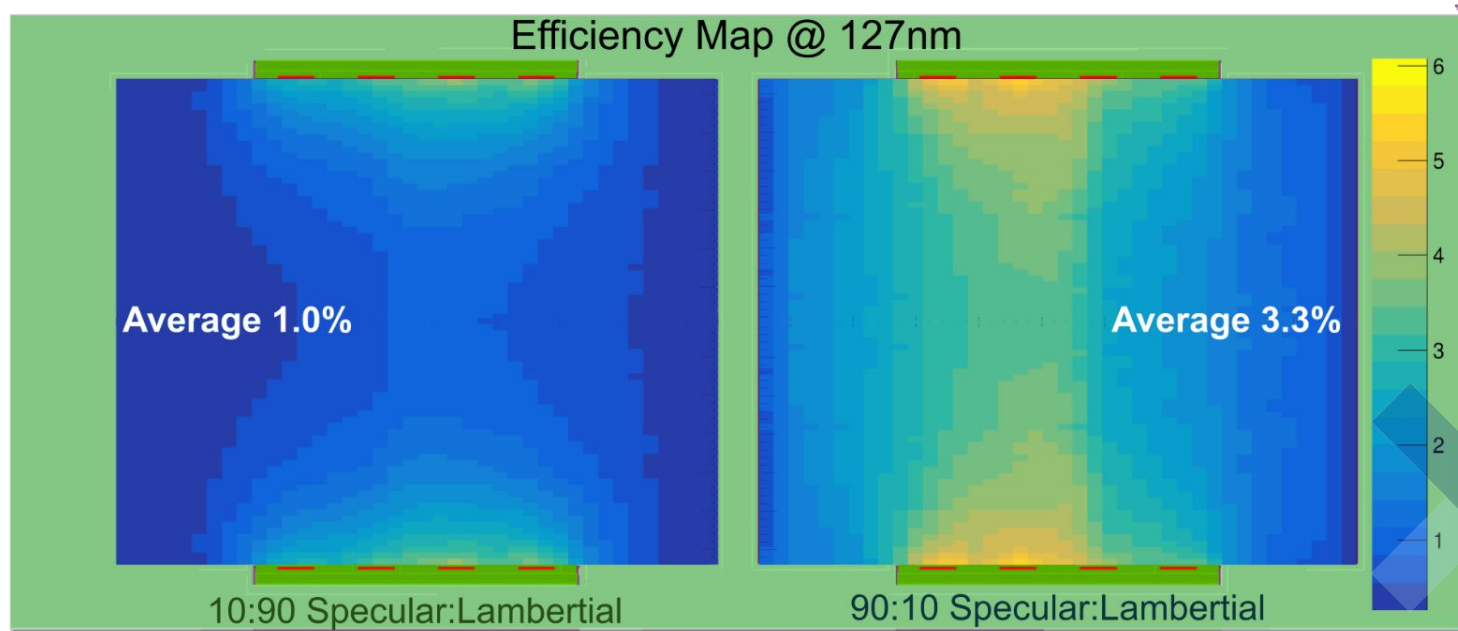

# Simulation Studies - Light dispersion

- Lambertian vs. Specular
- How much does it affect the efficiency?

# Simulation Studies - Light dispersion

# Simulation Studies - Light dispersion

- Specularity inside the light guide seems to be around 0.8 and 0.9, given the current efficiency measurements.
- A 10% variation of specularity in this range is not visible to the naked eye, but may explain some models being up to  $\pm 0.5\%$  in efficiency.

# Simulation Studies - Untrapping

SiPM

varying cut depth

6mm deep cut  
2x untrapped  
photons

# Simulation Studies - Light dispersion
