Higgs Physics at the LHC – Introduction

Ricardo Gonalo – UC/LIP

IDPASC Course on Physics at the LHC – LIP, 5 April 2023

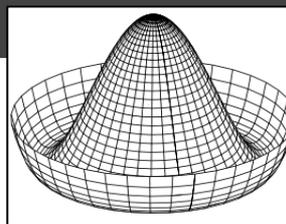

# Higgs Lectures

MONDAY, 4 APRIL

17:00 → 18:30 Higgs Physics 1

Introduction  
Reminder of some shortcomings of the SM: masses, WW scattering.  
The Higgs mechanism. Production and decay of the Higgs boson at colliders: LEP, Tevatron and LHC.  
Previous searches at LEP and the Tevatron.

**Speakers:** Ricardo Goncalo, Ricardo Gonalo (U. Coimbra/LIP)

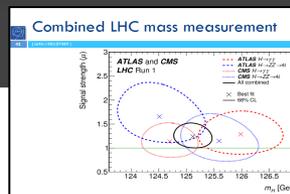

WEDNESDAY, 6 APRIL

17:00 → 18:30 Higgs Physics 2

Discovery of the Higgs boson in the different final states:  
Algorithms, challenges, tools,  
combination of results

**Speakers:** Pedro Silva (LIP), Pedro Vieira De Castro Ferreira Da Silva (CERN)

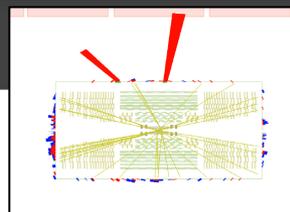

MONDAY, 11 APRIL

17:00 → 18:30 Higgs Physics 3

Case-study of the H→bb search, H→bb observation  
Algorithms, challenges, tools  
Higgs measurements with H→bb

**Speakers:** Rute Costa Batalha Pedro (LIP Laboratorio de Instrumentacao e Fisica Experimental de Particulas (PT)), Rute Pedro (LIP)

WEDNESDAY, 13 APRIL

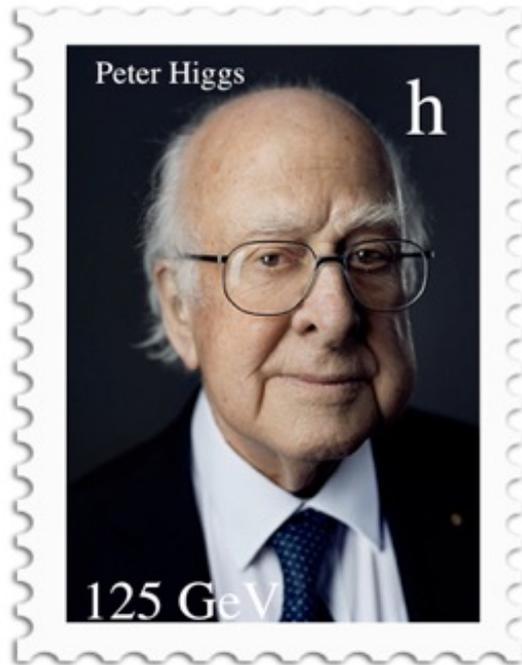

17:00 → 18:30 Higgs Physics 4

- Search for new physics in the Higgs sector.
- The Higgs boson and processes beyond the SM.
- Extensions of the SM, minimal and non-minimal extensions.
- High mass searches.
- MSSM Higgs searches: neutral, charged.
- Light pseudoscalar, resonant and non-resonant Higgs pair production.

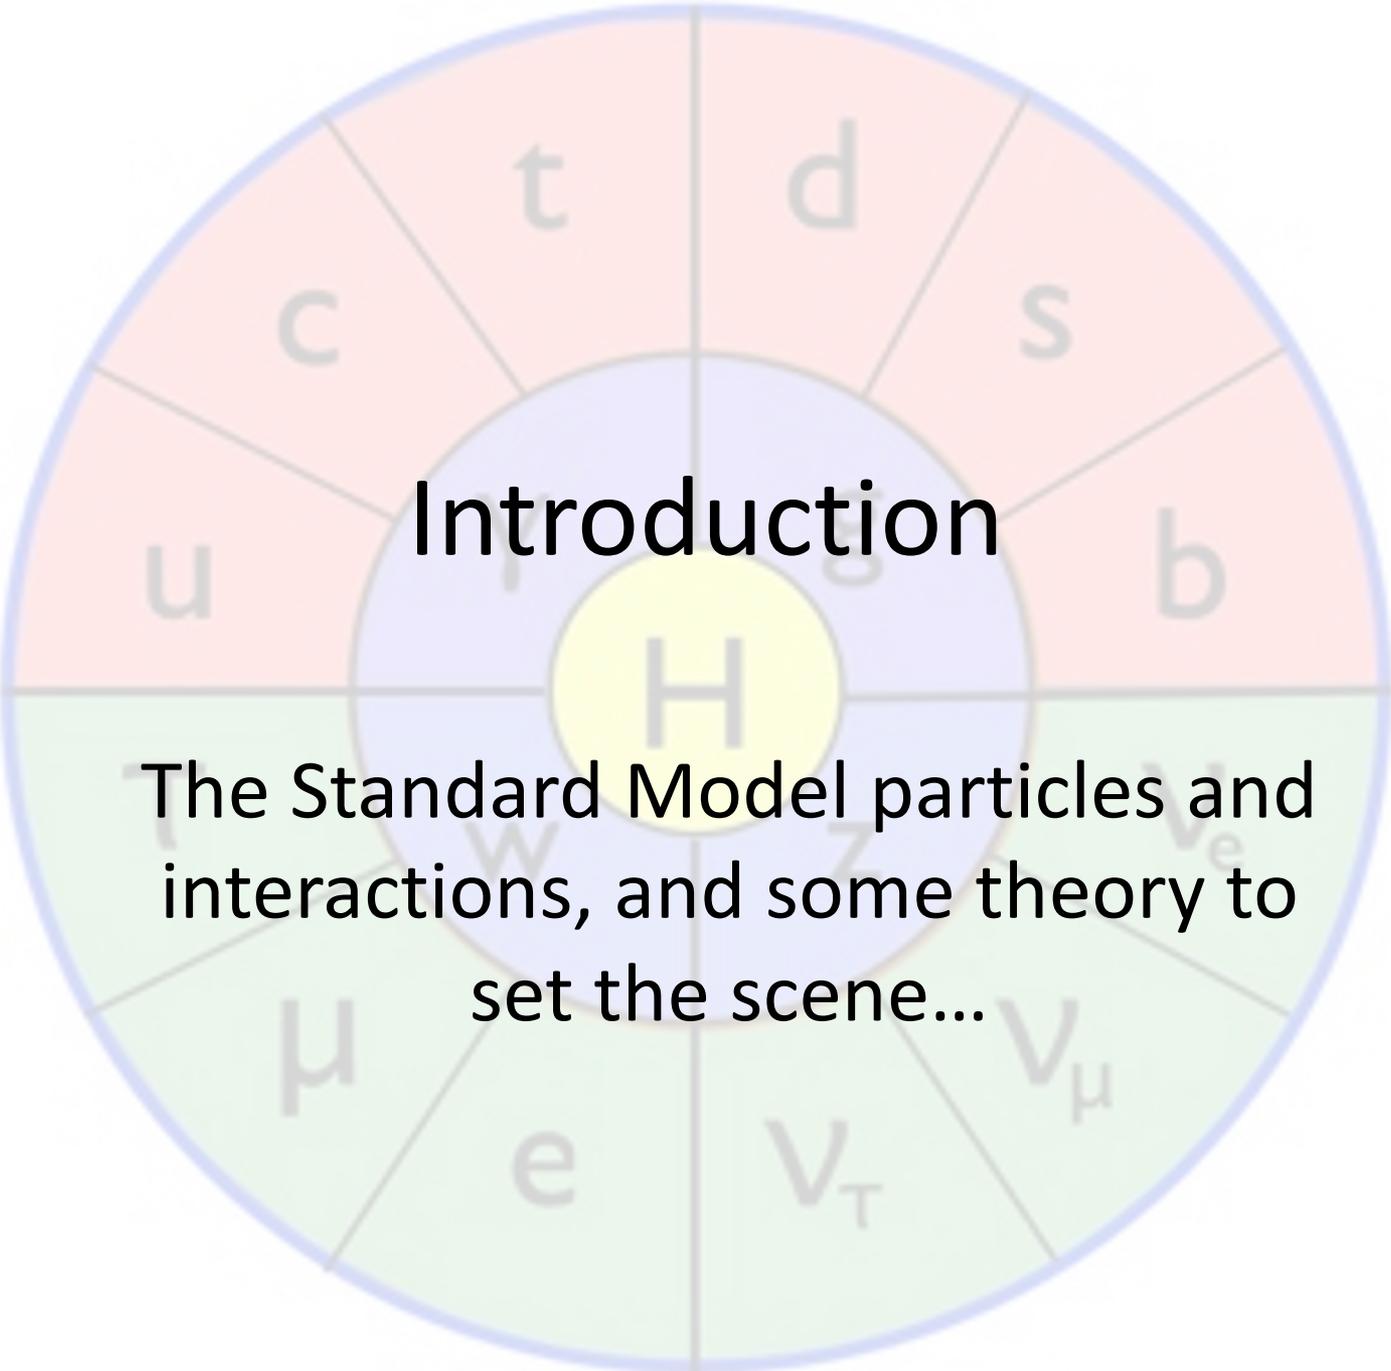

**Speaker:** Michele Gallinaro (LIP)

# Outlook

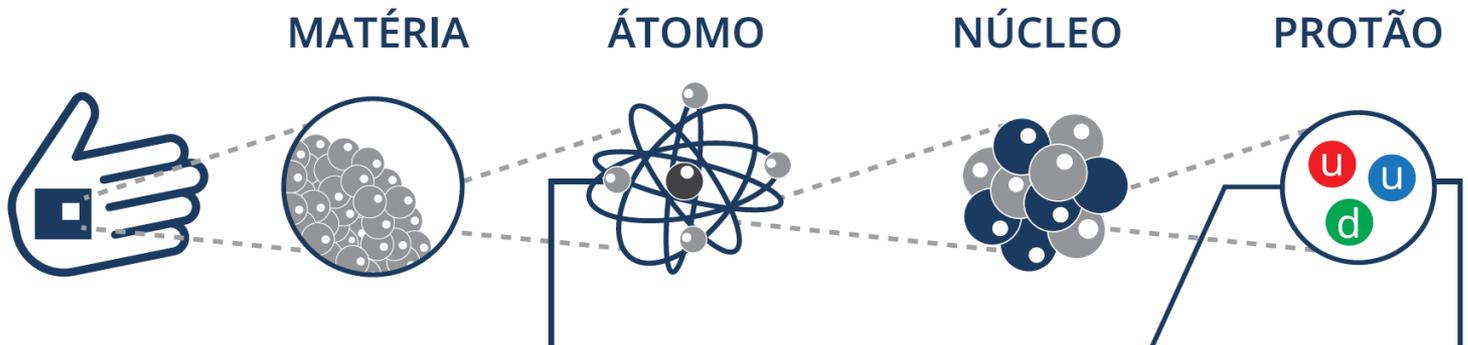

- What is the Higgs boson and what is it good for?
- How did we find it?
- Why do we care?
- And what comes next?

# Introduction

The Standard Model particles and interactions, and some theory to set the scene...

  - Acts on weak isospin
- Strong:
  - Carried by 8 gluons
  - Acts on colour

# Lagrangians, symmetries and all that

Leonhard Euler(1707–1783)

Emmy Noether (1882 – 1935)

Joseph-Louis Lagrange (1736–1813)

# Lagrangians in classical mechanics

The equations of motion of a system are derived from a scalar **Lagrangian** function of **generalized coordinates** and **velocities** (time derivatives of the coordinates)

$$L(q, \dot{q}) = T - V$$

From minimizing the action  $S$ , get the **Euler-Lagrange equations**:

$$S = \int dt L(q_i, \dot{q}_i) \quad \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0$$

For a point particle in a potential  $U$ , with  $q_i = x, y, z$

$$L = \frac{1}{2} m \dot{q}_i^2 - U(q_i) \quad \frac{d}{dt} (m \dot{q}_i) + \frac{\partial U}{\partial q_i} = 0 \quad m \ddot{q}_i = - \frac{\partial U}{\partial q_i}$$

# Symmetries and conservation laws

Noether's theorem:

If a system has a continuous symmetry property, then there are corresponding quantities whose values are conserved in time.

Simplest case:

Coordinates not explicitly appearing in the Lagrangian =>  
Lagrangian invariant over a transformation of these coordinates

Example: point mass  $m$  orbiting in the field of a fixed mass  $M$

$$L(r, \phi, \dot{r}, \dot{\phi}) = T - V = \frac{1}{2}m\dot{r}^2 + \frac{1}{2}mr^2\dot{\phi}^2 + \frac{GMm}{r}$$

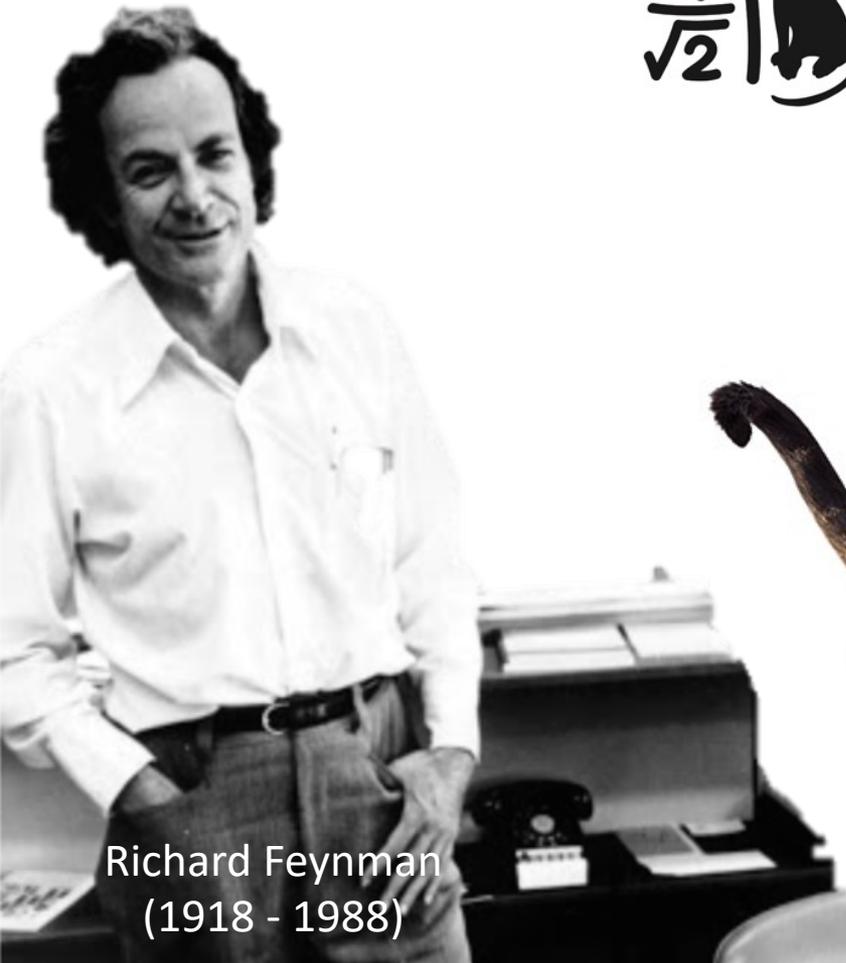

Since the lagrangian doesn't depend explicitly on  $\phi$  (symmetry with respect to rotations in space), the Euler-Lagrange equation gives

$$\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\phi}} \right) = 0 \Leftrightarrow \frac{\partial L}{\partial \dot{\phi}} = mr^2\dot{\phi} = J$$

Where the angular momentum  $J$  is a constant of motion!

# Let's go to quantum fields...

$$\frac{1}{\sqrt{2}}|\text{cat}\rangle + \frac{1}{\sqrt{2}}|\text{cat}\rangle$$

Richard Feynman  
(1918 - 1988)

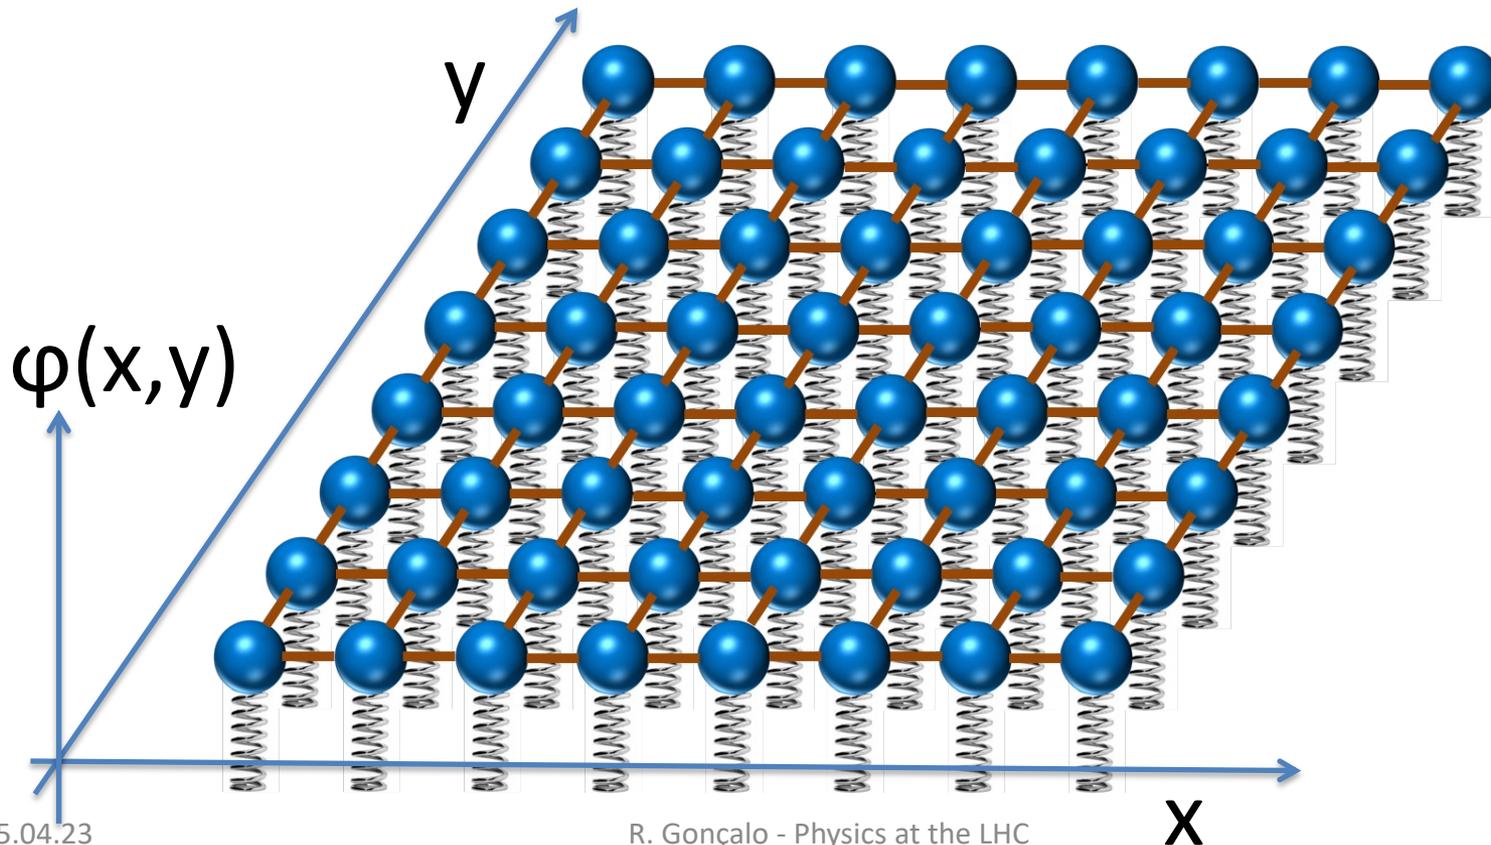

Fluffy (?-?)

Erwin  
Schrödinger  
(1887 - 1961)

# Now in quantum field theory...

Imagine space as an infinite continuum of balls and springs, where each ball is connected to its neighbours by elastic bands. **Particles are perturbations of this field**

Generalized coordinates are now **fields** (dislocation of each spring)

$$q_i \rightarrow \phi_i(x^\mu)$$

In a relativistic theory we must treat space and time coordinates on an equal footing, so the derivatives in the classical equations are now

$$\frac{d}{dt}, \nabla \rightarrow \partial_\mu = \left( \frac{\partial}{\partial t}, \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right)$$

In place of a Lagrangian we have a **Lagrangian density** (we call it Lagrangian anyway, just to be confusing)

$$L(q_i, \frac{dq_i}{dt}) \rightarrow \mathcal{L}(\phi_i, \partial_\mu \phi_i) \quad \text{with: } L = \int \mathcal{L} d^3 \mathbf{x}$$

The new Euler-Lagrange equation now becomes

$$\partial_\mu \left( \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi_i)} \right) - \frac{\partial \mathcal{L}}{\partial \phi_i} = 0$$

- Example Lagrangians and equations of motion:
- Klein-Gordon Lagrangian for spin 0 particles (scalars):

$$\mathcal{L}_{KG} = \frac{1}{2}(\partial_\mu \phi)(\partial^\mu \phi) - \frac{1}{2}m^2 \phi^2$$

$$\partial_\mu \partial^\mu \phi + m^2 \phi = 0$$

- Dirac Lagrangian for spin 1/2 particles (fermions):

$$\mathcal{L}_D = i\bar{\psi}\gamma^\mu \partial_\mu \psi - m\bar{\psi}\psi$$

$$i\gamma^\mu \partial_\mu \psi - m\psi = 0$$

- Proca Lagrangian for spin 1 (vector) particles:

$$\mathcal{L}_P = \frac{-1}{16\pi}(\partial^\mu A^\nu - \partial^\nu A^\mu)(\partial_\mu A_\nu - \partial_\nu A_\mu) + \frac{1}{8\pi}m^2 A^\nu A_\nu$$

$$\partial_\mu(\partial^\mu A^\nu - \partial^\nu A^\mu) + m^2 A^\nu = 0$$

- Important:

Mass terms in Lagrangian are quadratic in the fields

# Global gauge invariance

Take the Dirac Lagrangian for a spinor field  $\psi$  representing a spin- $\frac{1}{2}$  particle, for example an electron:

$$\mathcal{L} = i\hbar\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi$$

It is invariant under a global U(1) phase transformation like:

$$\psi(x) \rightarrow \psi'(x) = e^{iq\chi}\psi(x)$$

Where  $\chi$  is a constant

$$\mathcal{L}' = e^{-iq\chi}e^{iq\chi}(i\hbar\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi) = \mathcal{L}$$

Note: gauge invariance of the Dirac equation can be demonstrated to lead to conservation of probability current  $j^\mu$

$$j^\mu = (\rho, \mathbf{J}) = \bar{\psi}\gamma^\mu\psi$$

# Local gauge invariance and interactions

If  $\chi = \chi(x)$  then we get extra terms in the Lagrangian:

$$\begin{aligned}\mathcal{L}' &= ie^{-iq\chi}\bar{\psi}\gamma^\mu[e^{iq\chi}\partial_\mu\psi + iq(\partial_\mu\chi)e^{iq\chi}\psi] - me^{-iq\chi}e^{iq\chi}\bar{\psi}\psi \\ &= \mathcal{L} - q\bar{\psi}\gamma^\mu(\partial_\mu\chi)\psi\end{aligned}$$

But we can now make the Lagrangian invariant by adding an **interaction term** with a new **gauge** field  $\mathbf{A}_\mu$  which transforms as:

$$A_\mu \rightarrow A'_\mu = A_\mu - \partial_\mu\chi$$

We get:

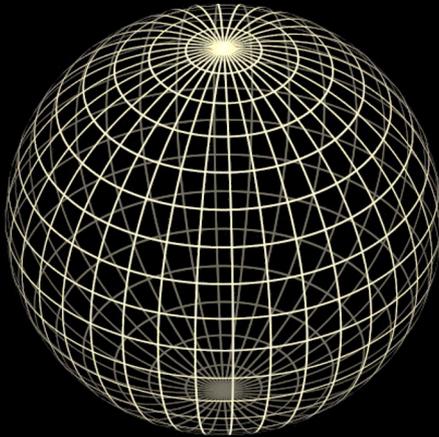

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi - q\bar{\psi}\gamma^\mu A_\mu\psi$$

Note:

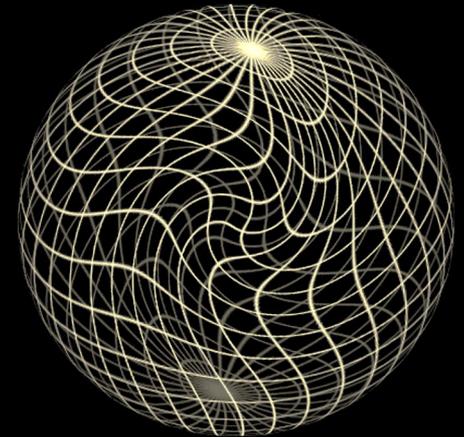

1. The new gauge field  $A_\mu$  is the photon in QED
2. The mass of the fermion is the coefficient of the term on  $\bar{\psi}\psi$
3. There is no term in  $A_\mu A^\mu$  (the photon has zero mass)

$$\psi(x) \rightarrow \psi'(x) = e^{iq\chi} \psi(x)$$

Original sphere

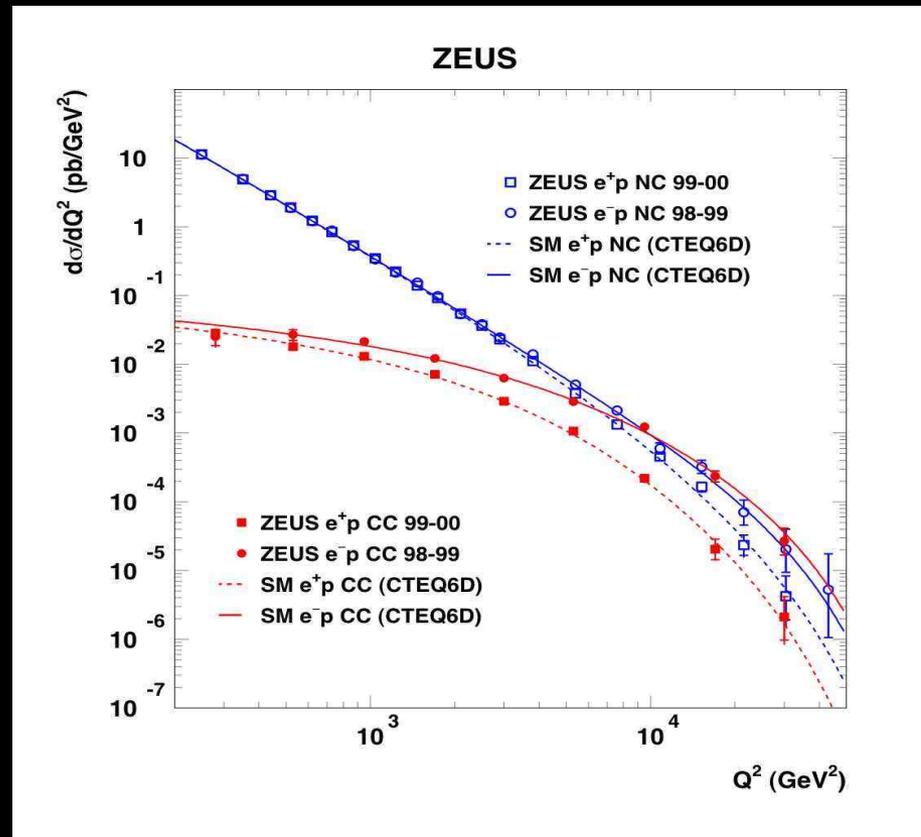

Local transformação

$\chi = \text{constant}$

$\chi = \chi(x)$

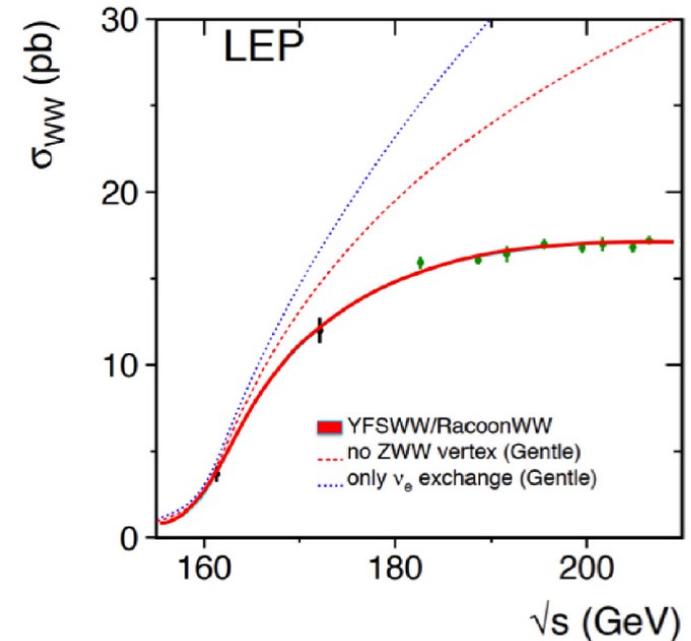

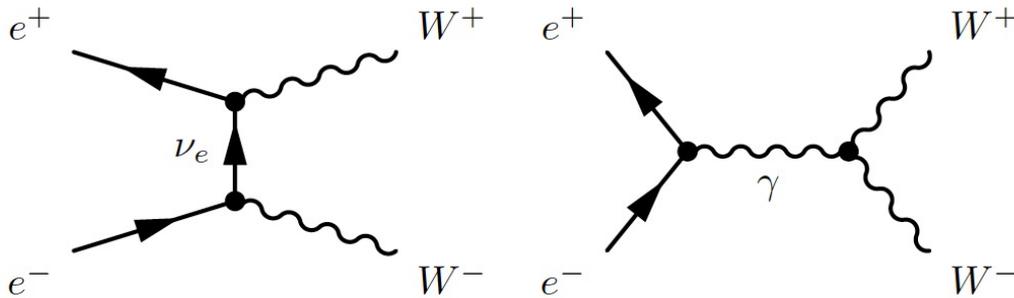

# Weak Neutral Currents and Electroweak Unification

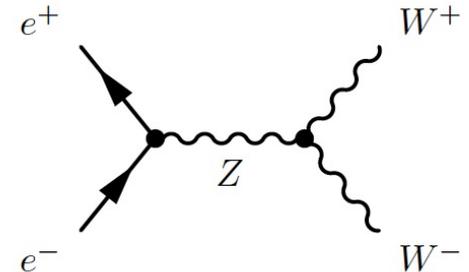

# Weak Charged and Neutral Currents

- Weak CC interactions explained by  $W^\pm$  boson exchange
- $W^\pm$  bosons are charged, thus they couple to the  $\gamma$

Consider  $e^-e^+ \rightarrow W^+W^-$ : 2 diagrams (+interference)

- Cross-section **diverges** at high energy
- Divergence cured by introducing  $Z$  boson
- Extra diagram for  $e^-e^+ \rightarrow W^+W^-$
- Idea only works if  $\gamma$ ,  $W^\pm$ ,  $Z$  couplings are related

# Weak Gauge Theory

- Postulate invariance under a gauge transformation like:

$$\psi \rightarrow \psi' = e^{ig\vec{\sigma}\cdot\vec{\Lambda}(\vec{r},t)}\psi$$

an “SU(2)” transformation ( $\sigma$  are 2x2 matrices).

- Operates on the state of “weak isospin” – a “rotation” of the isospin state.
- Invariance under SU(2) transformations  $\Rightarrow$  three massless gauge bosons ( $W_1, W_2, W_3$ ) whose couplings are well specified.
- They also have self-couplings.

But this doesn't quite work...

Predicts  $W$  and  $Z$  have the same couplings – not seen experimentally!

# Sheldon Glashow's “stumbling block”

## PARTIAL-SYMMETRIES OF WEAK INTERACTIONS

SHELDON L. GLASHOW †

*Institute for Theoretical Physics, University of Copenhagen, Copenhagen, Denmark*

Received 9 September 1960

**Abstract:** Weak and electromagnetic interactions of the leptons are examined under the hypothesis that the weak interactions are mediated by vector bosons. With only an isotopic triplet of leptons coupled to a triplet of vector bosons (two charged decay-intermediaries and the photon) the theory possesses no partial-symmetries. Such symmetries may be established if additional vector bosons or additional leptons are introduced. Since the latter possibility yields a theory disagreeing with experiment, the simplest partially-symmetric model reproducing the observed electromagnetic and weak interactions of leptons requires the existence of at least four vector-boson fields (including the photon). Corresponding partially-conserved quantities suggest leptonic analogues to the conserved quantities associated with strong interactions: strangeness and isobaric spin.

### 1. Introduction

At first sight there may be little or no similarity between electromagnetic effects and the phenomena associated with weak interactions. Yet certain remarkable parallels emerge with the supposition that the weak interactions are mediated by unstable bosons. Both interactions are universal, for only a single coupling constant suffices to describe a wide class of phenomena: both interactions are generated by vectorial Yukawa couplings of spin-one fields ††. Schwinger first suggested the existence of an “isotopic” triplet of vector fields whose universal couplings would generate both the weak interactions and electromagnetism — the two oppositely charged fields mediate weak interactions and the neutral field is light <sup>2</sup>). A certain ambiguity beclouds the self-interactions among the three vector bosons; these can equivalently be interpreted as weak or electromagnetic couplings. The more recent accumulation of experimental evidence supporting the  $\Delta I = \frac{1}{2}$  rule characterizing the non-leptonic decay modes of strange particles indicates a need for at least one additional neutral intermediary <sup>3</sup>).

The mass of the charged intermediaries must be greater than the K-meson mass, but the photon mass is zero — surely this is the principal stumbling block in any pursuit of the analogy between hypothetical vector mesons and photons. It is a stumbling block we must overlook. To say that the decay intermediaries

- There are hints that EM and weak interactions have a common origin
  - Similar gauge structure
  - $W^\pm$  couples to charge
- But there are obvious differences:
  - Different masses of  $W^\pm$ , Z and photon
  - Structure of the vertex is different

# The GWS Model

The **G**lashow, **W**einberg and **S**alam model treats **EM** and **weak** interactions as different manifestations of a single **unified electroweak** force (Nobel Prize 1979)

Start with 4 massless bosons  $W^+$ ,  $W_3$ ,  $W^-$  and  $B$ . The neutral bosons **mix** to give physical bosons (the particles we see), i.e. the  $W^\pm$ ,  $Z$ , and  $\gamma$ .

$$\begin{pmatrix} W^+ \\ W_3 \\ W^- \end{pmatrix}; B \rightarrow \begin{pmatrix} W^+ \\ Z \\ W^- \end{pmatrix}; \gamma$$

Physical fields:  $W^+$ ,  $Z$ ,  $W^-$  and  $A$  (photon).

$$Z = W_3 \cos \theta_W - B \sin \theta_W$$

$$A = W_3 \sin \theta_W + B \cos \theta_W$$

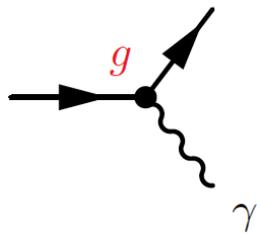

$\theta_W$  Weak Mixing Angle

$W^\pm$ ,  $Z$  “acquire” mass via the **Higgs mechanism**.

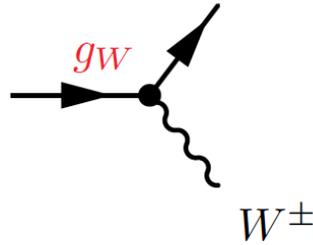

# The GWS Model

The beauty of the **GWS** model is that it makes **exact** predictions of the  $W^\pm$  and  $Z$  masses and of their couplings with **only 3** free parameters.

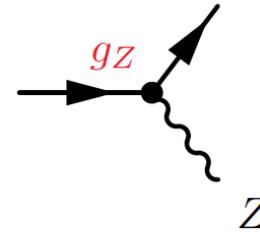

**Couplings given by  $\alpha_{EM}$  and  $\theta_W$**

$$\alpha_{EM} = \frac{e^2}{4\pi} \quad g \sim e$$

$$g_W = \frac{e}{\sin \theta_W}$$

$$g_Z = \frac{e}{\sin \theta_W \cos \theta_W} = \frac{g_W}{\cos \theta_W}$$

**Masses also given by  $G_F$  and  $\theta_W$**

From Fermi theory

$$\frac{G_F}{\sqrt{2}} = \frac{g_W^2}{8m_W^2} = \frac{e^2}{8m_W^2 \sin^2 \theta_W} \quad m_{W^\pm} = \left( \frac{\sqrt{2}e^2}{8G_F \sin^2 \theta_W} \right)^{1/2} \quad m_Z = \frac{m_W}{\cos \theta_W}$$

If we know  $\alpha_{EM}$ ,  $G_F$ ,  $\sin \theta_W$  (from experiment), everything else is defined.

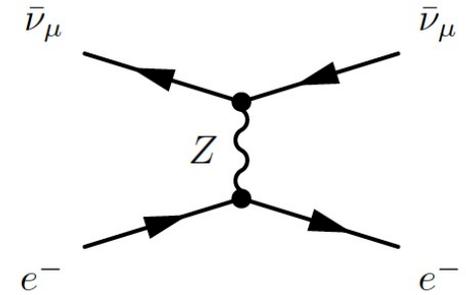

# Evidence for the GWS model

- **Discovery of Neutral Currents (1973)**

The process  $\bar{\nu}_\mu e^- \rightarrow \bar{\nu}_\mu e^-$  was observed.

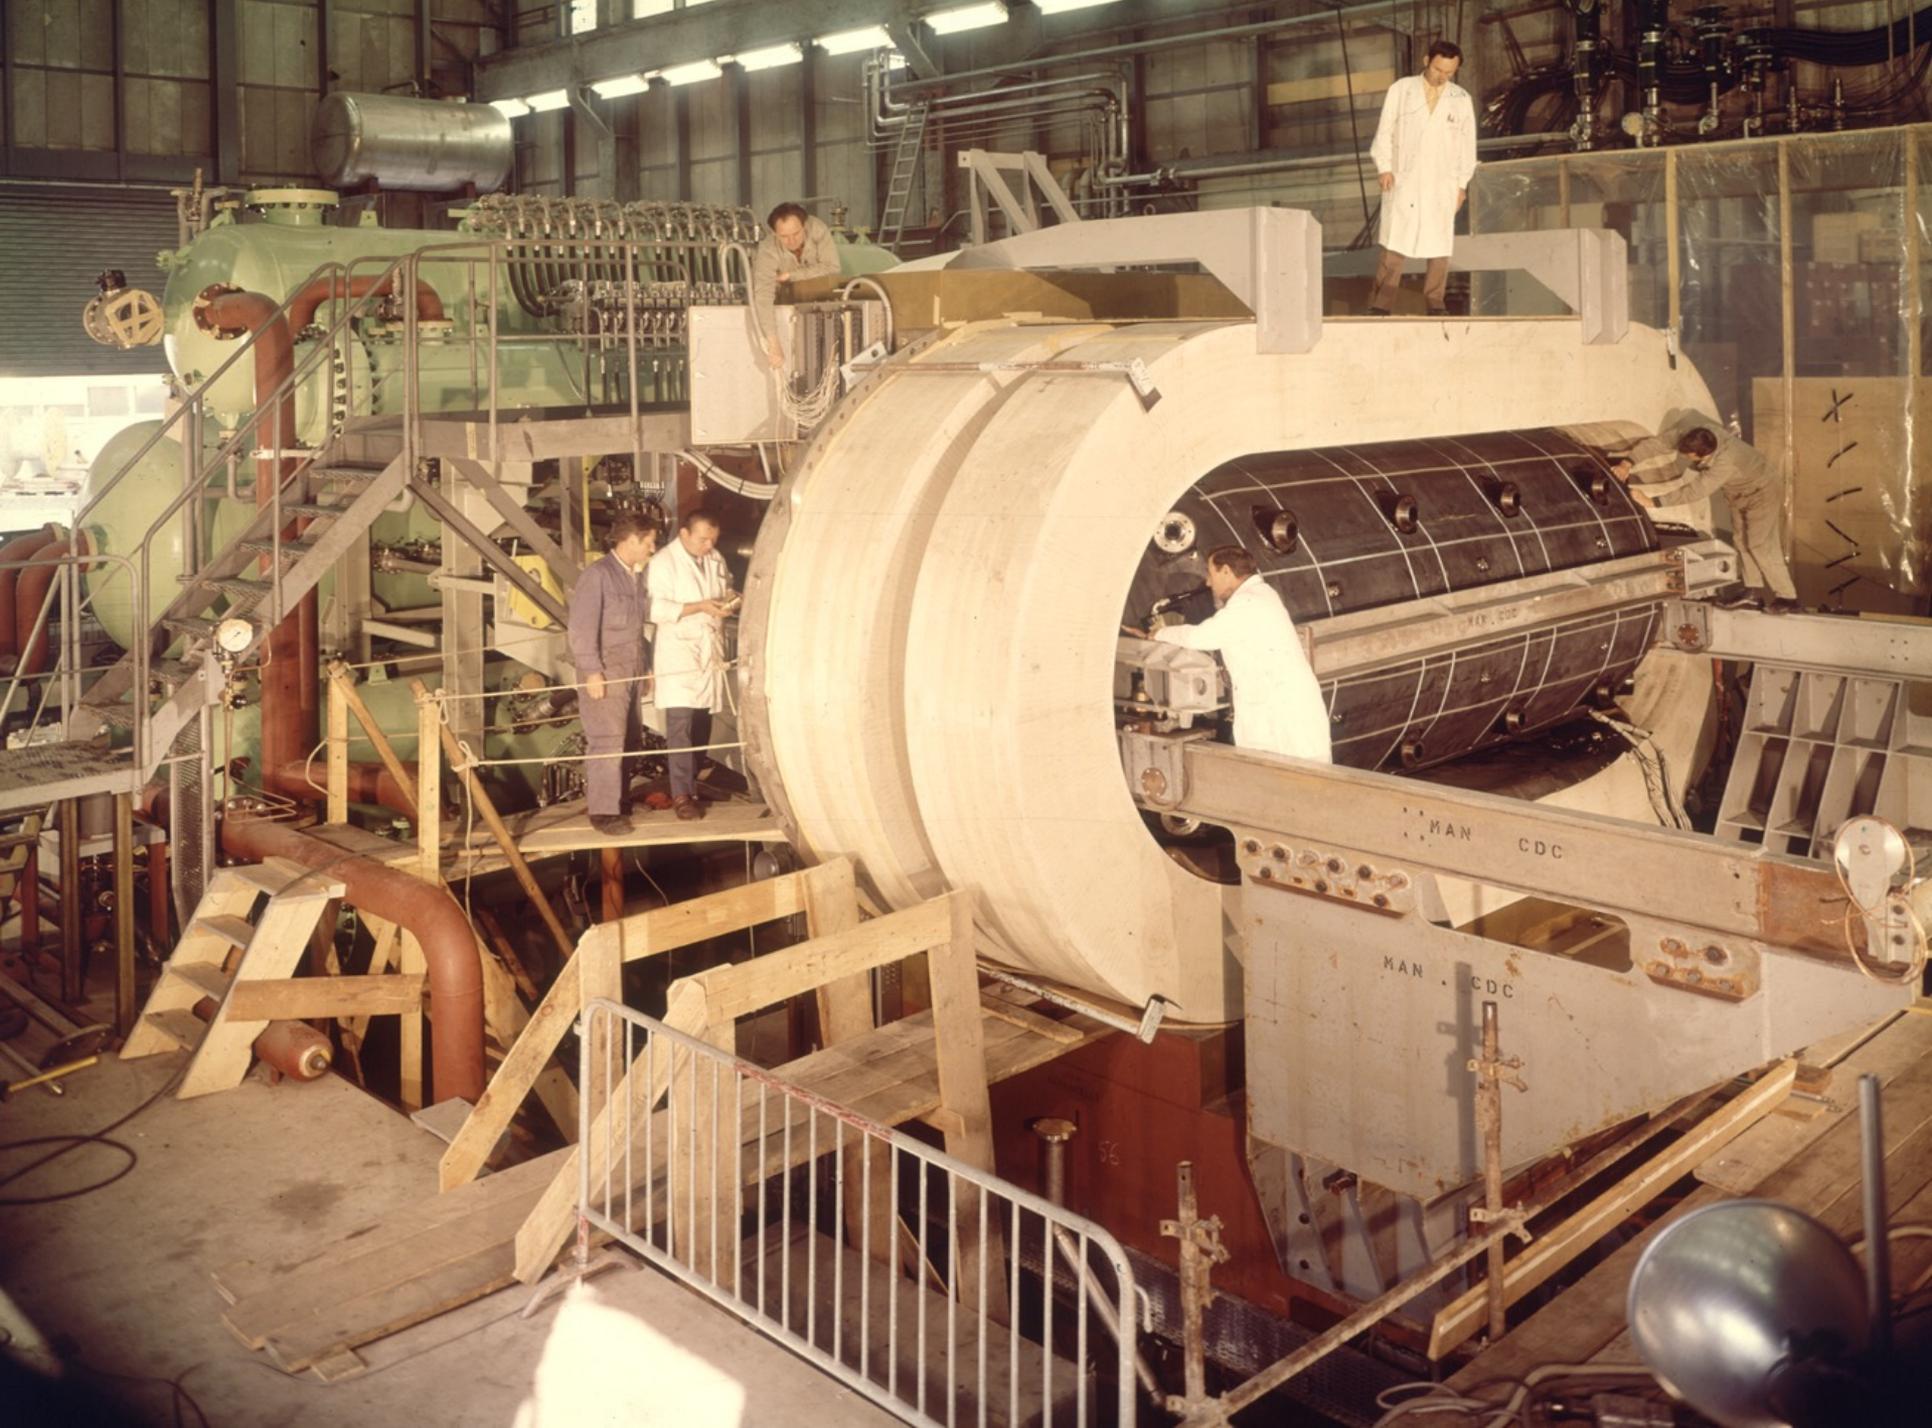

**Only** possible Feynman diagram (no  $W^\pm$  diagram).

Indirect evidence for  $Z$ .

 \end{array}$$

- **Precision Measurements of the Standard Model (1989-2000)**

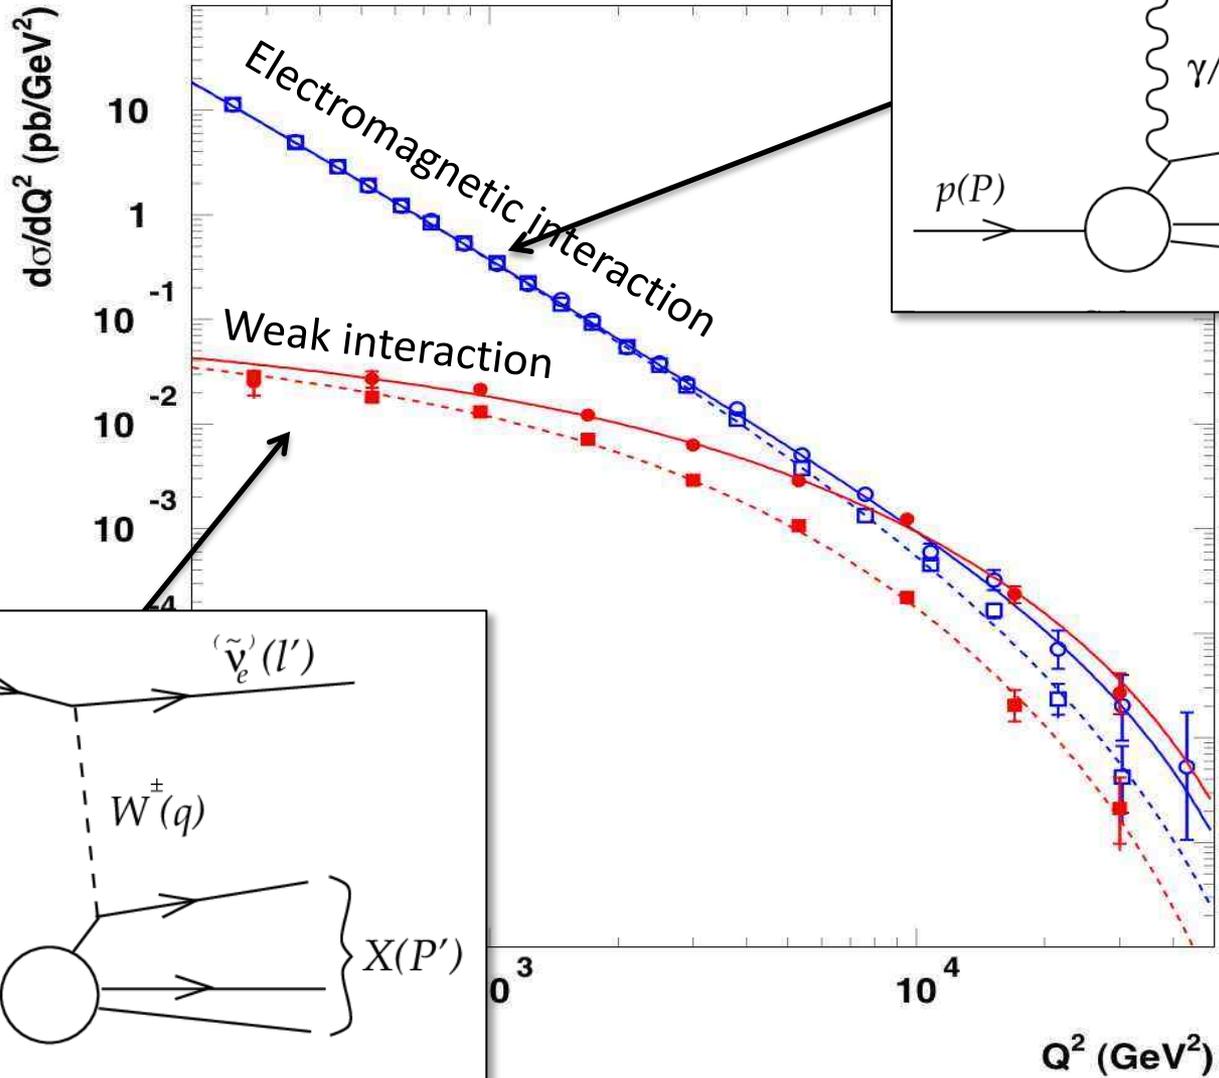

LEP  $e^+e^-$  collider provided many precision measurements of the Standard Model.

- Wide variety of different processes consistent with GWS model predictions and measure **same value** of

$$\sin^2 \theta_W = 0.23113 \pm 0.00015$$

$$\theta_W \sim 29^\circ$$

# ZEUS

Now for the problems...

## Problem 1: Mass of elementary particles and gauge bosons

What if we add a photon mass term to the QED Lagrangian?

$$\mathcal{L}_{QED} = \bar{\psi}(i\gamma^\mu \partial_\mu - m_e)\psi - e\bar{\psi}\gamma^\mu\psi A_\mu - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} + \frac{1}{2}m_\gamma A_\mu A^\mu$$

To keep the Lagrangian gauge invariant (against a local U(1) local phase transformation) the photon field transforms as:

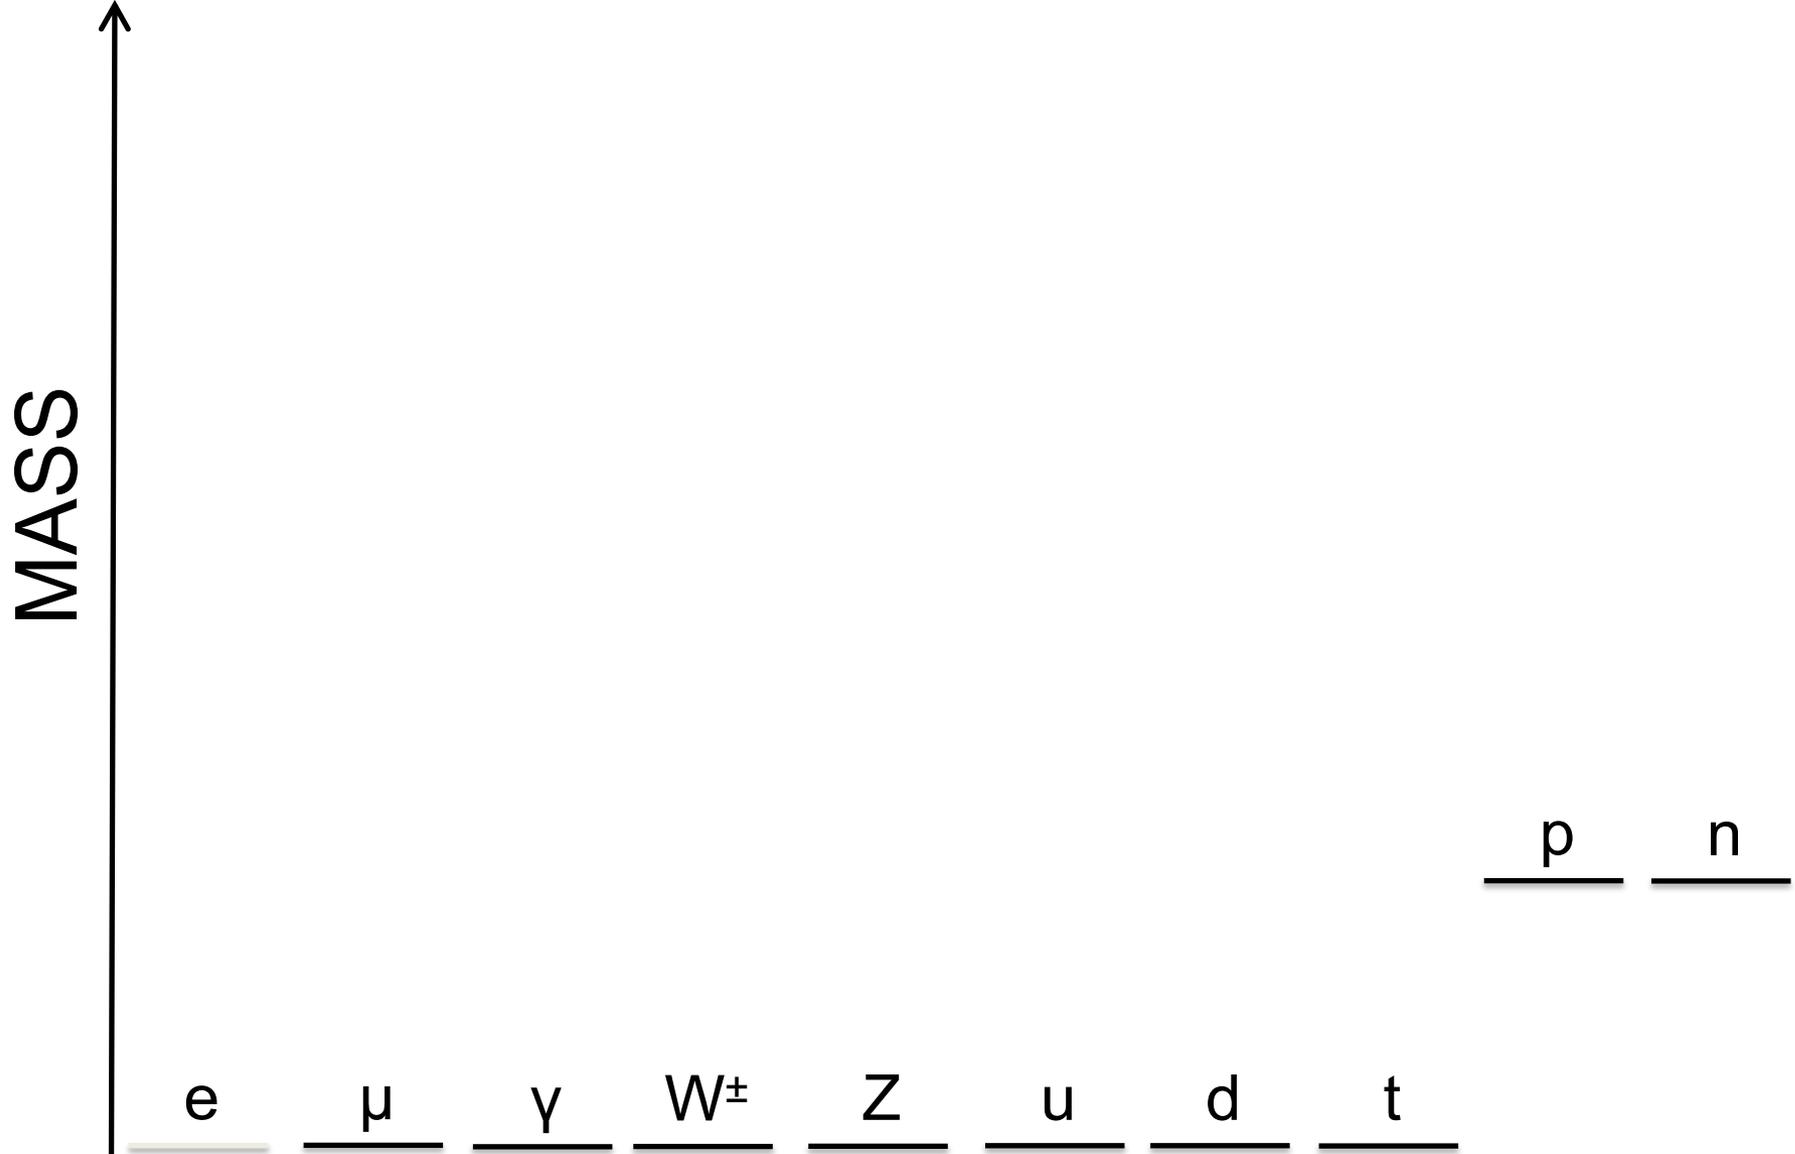

$$A_\mu \rightarrow A'_\mu = A_\mu - \partial_\mu \chi$$

But the  $A^\mu$  mass term breaks the Lagrangian invariance:

$$\frac{1}{2}m_\gamma A_\mu A^\mu \rightarrow \frac{1}{2}m_\gamma (A_\mu - \partial_\mu \chi)(A^\mu - \partial^\mu \chi) \neq \frac{1}{2}m_\gamma A_\mu A^\mu$$

For the  $SU(2)_L$  gauge symmetry transformations of the **weak interaction** the fermion mass term  $m_e \bar{\psi}\psi$  also breaks invariance!

# It should not work...

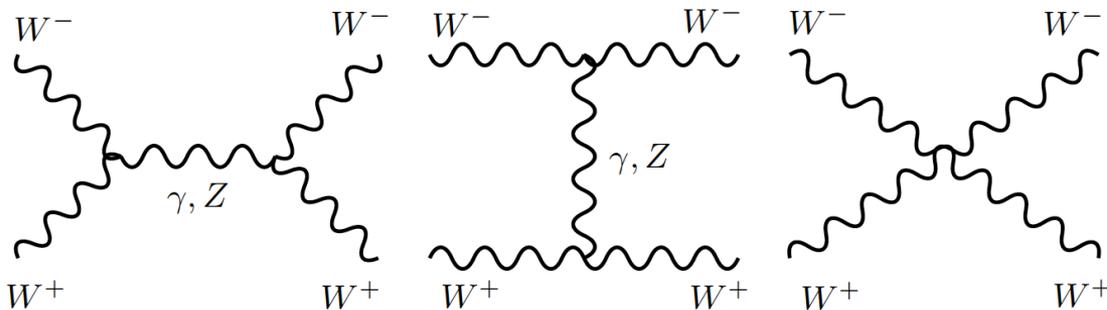

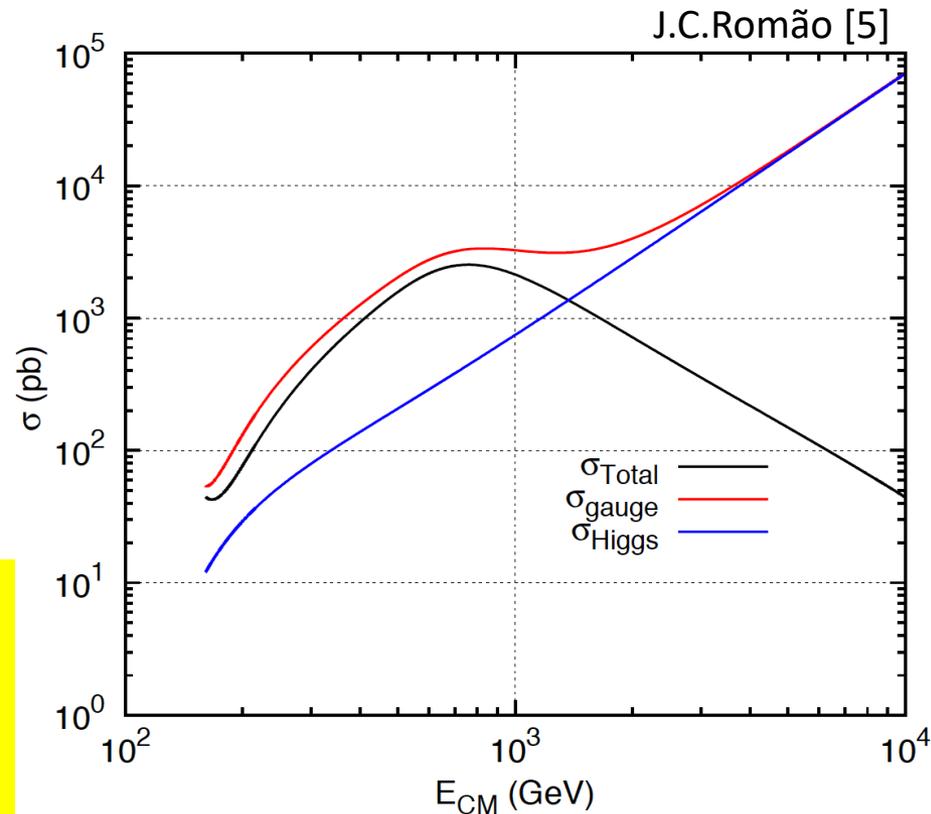

## Problem 2:

### Longitudinal gauge-boson scattering

In the absence of the Higgs, some processes have cross sections that grow with the centre of mass energy of the collision... i.e. breaks unitarity!

The Higgs regulates the cross section through negative interference

**Bottom line: the SM (without the Higgs mechanism) results in wrong calculations and breaks down for massive particles**

Feynman diagrams contributing to longitudinal WW scattering

# The Higgs Mechanism

Robert Brout (1928 – 2011)

Peter Higgs (b. 1929)

François Englert  
(b. 1932)

- Introduce a SU(2) doublet of spin-0 complex fields

$$\phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1 + i\phi_2 \\ \phi_3 + i\phi_4 \end{pmatrix}$$

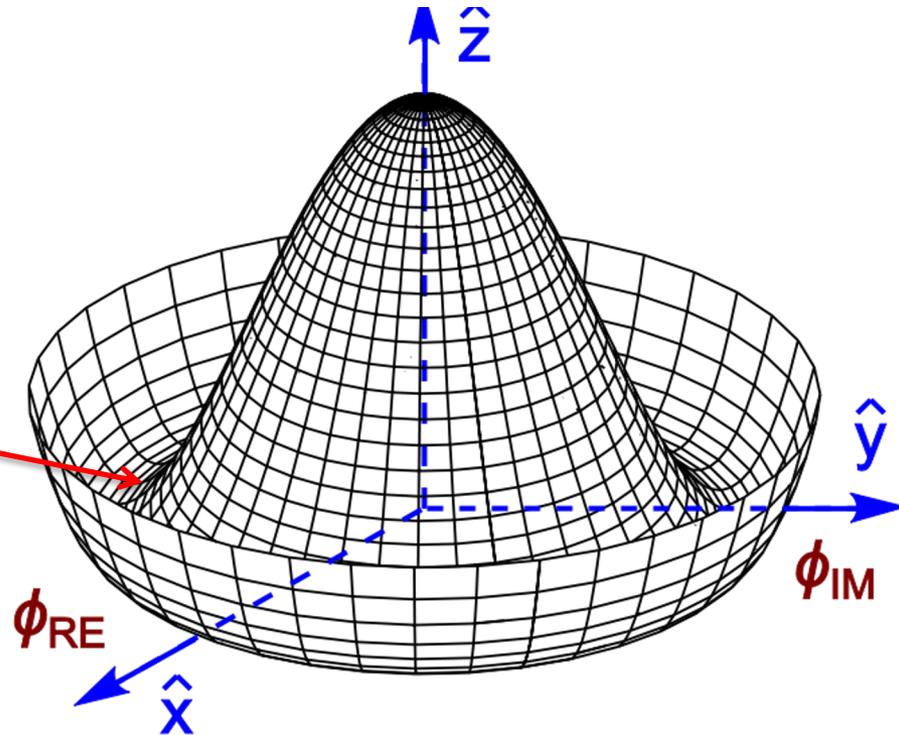

- New Lagrangian term:  $\mathcal{L} = (\partial_\mu \phi)^\dagger (\partial^\mu \phi) - V(\phi)$

- With a potential  $V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$

- For  $\lambda > 0, \mu^2 > 0$  the potential has a minimum at the origin
- For  $\lambda > 0, \mu^2 < 0$  the potential has an infinite number of minima at:

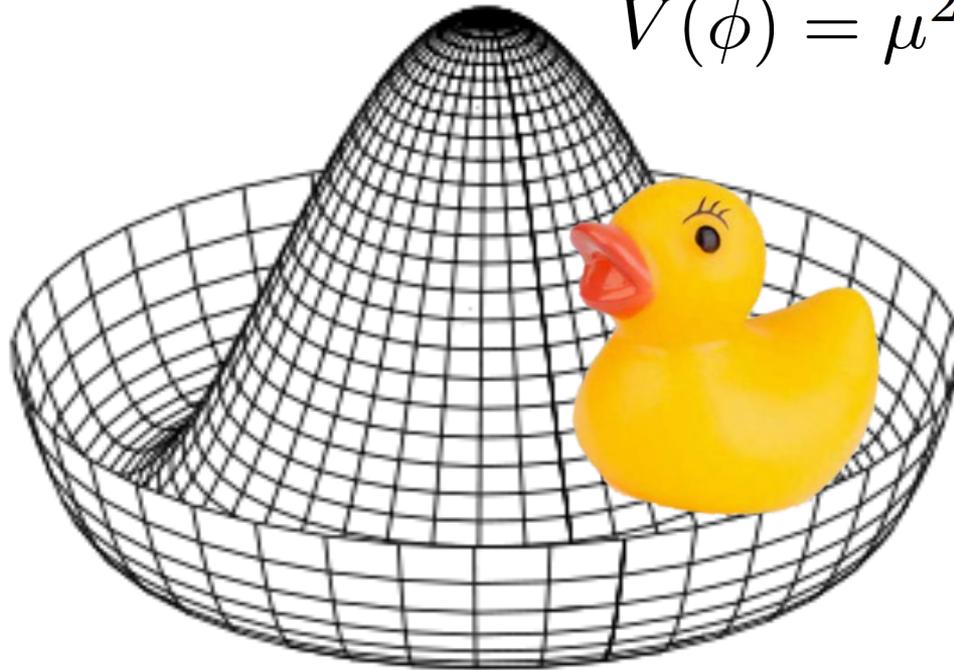

$$|\phi| = \frac{v}{\sqrt{2}} = \sqrt{-\frac{\mu^2}{2\lambda}}$$

The choice of vacuum (lowest energy state of the field) breaks the symmetry of the Lagrangian

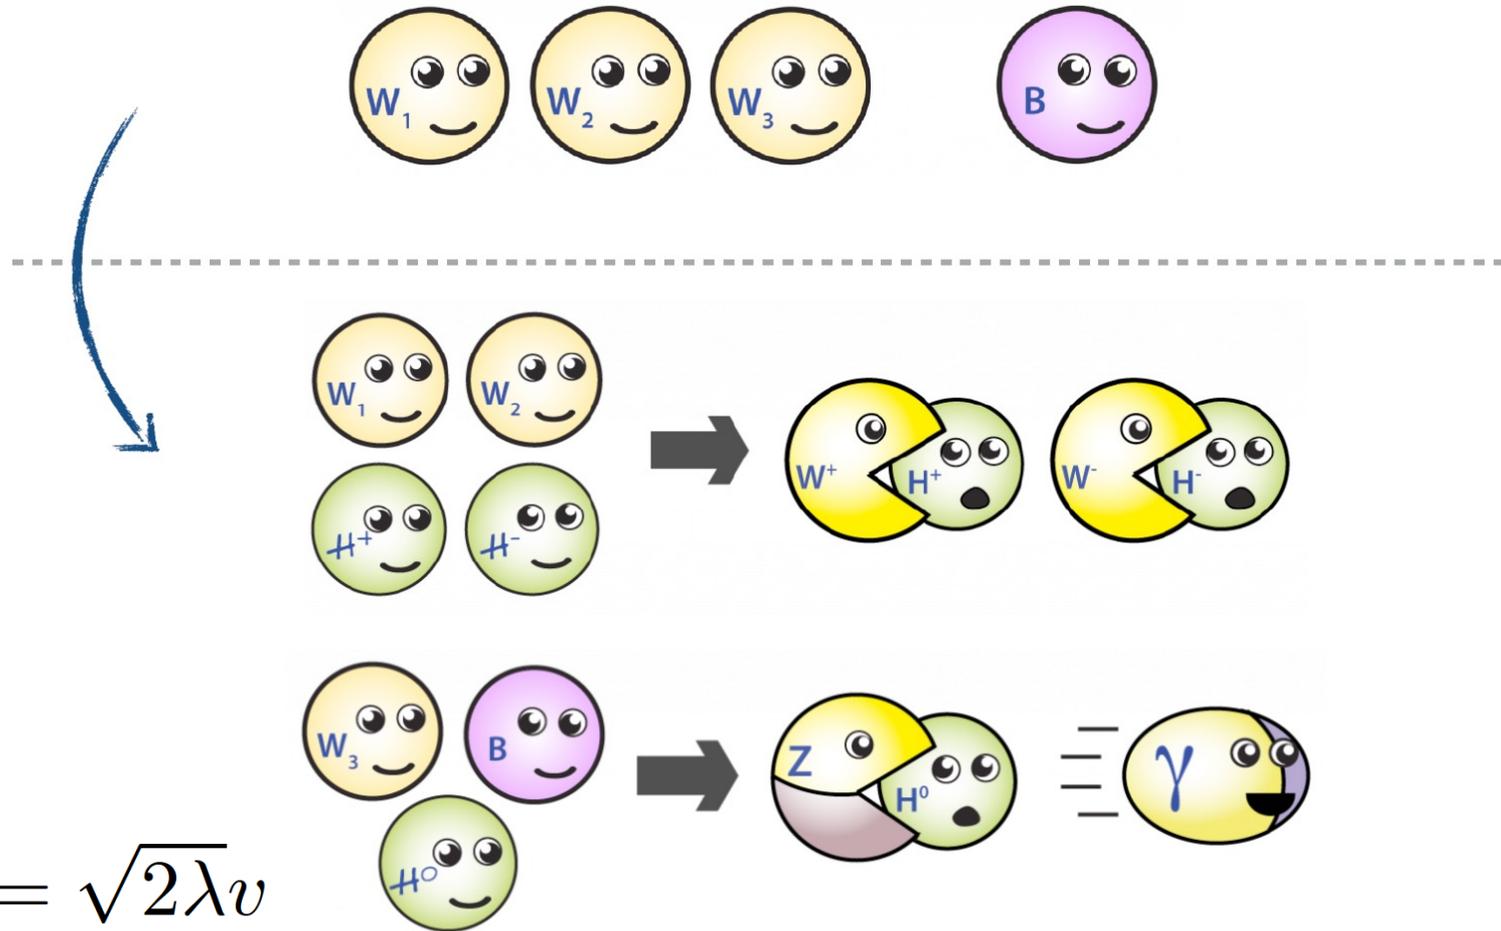

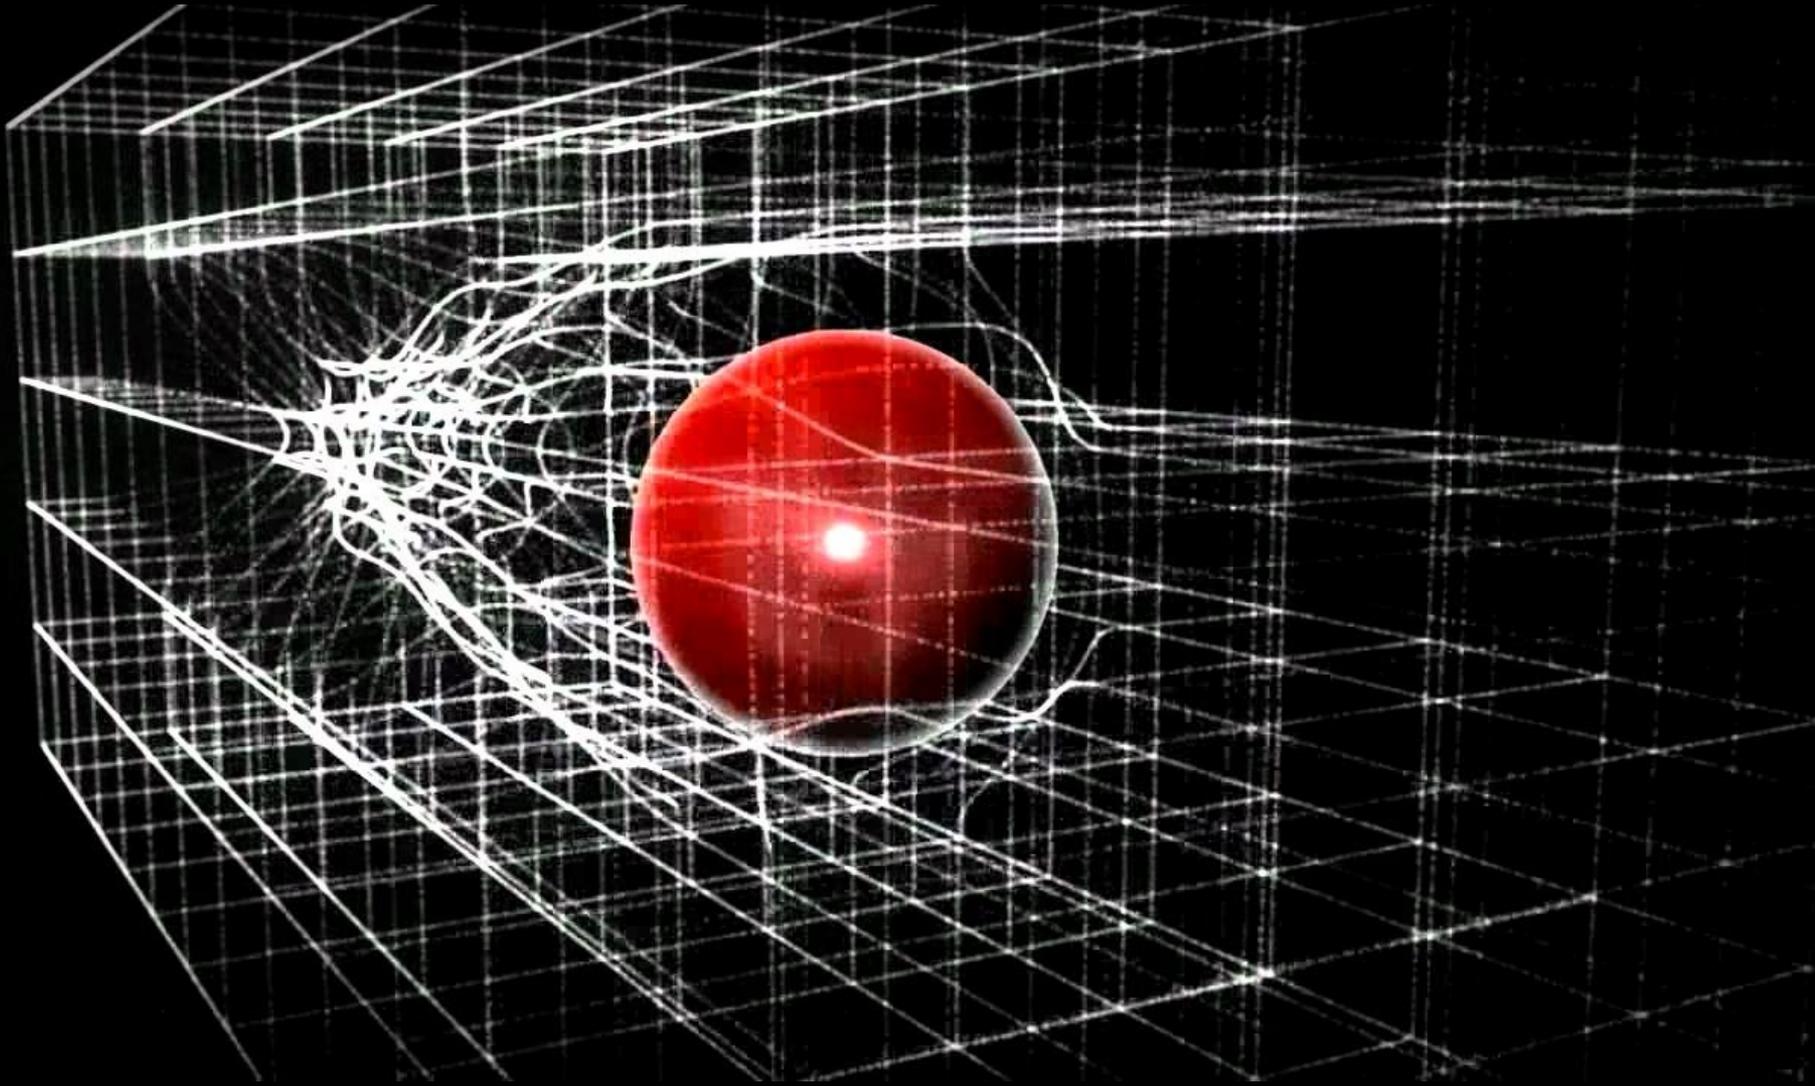

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

# EWK Symmetry Breaking in Pictures

$$m_h = \sqrt{2\lambda}v$$

# Higgs Properties

- Mass  $m_h = \sqrt{2\lambda}v$
- Spin: 1 degree of freedom  $\Rightarrow 0$
- Couplings:
- To gauge bosons

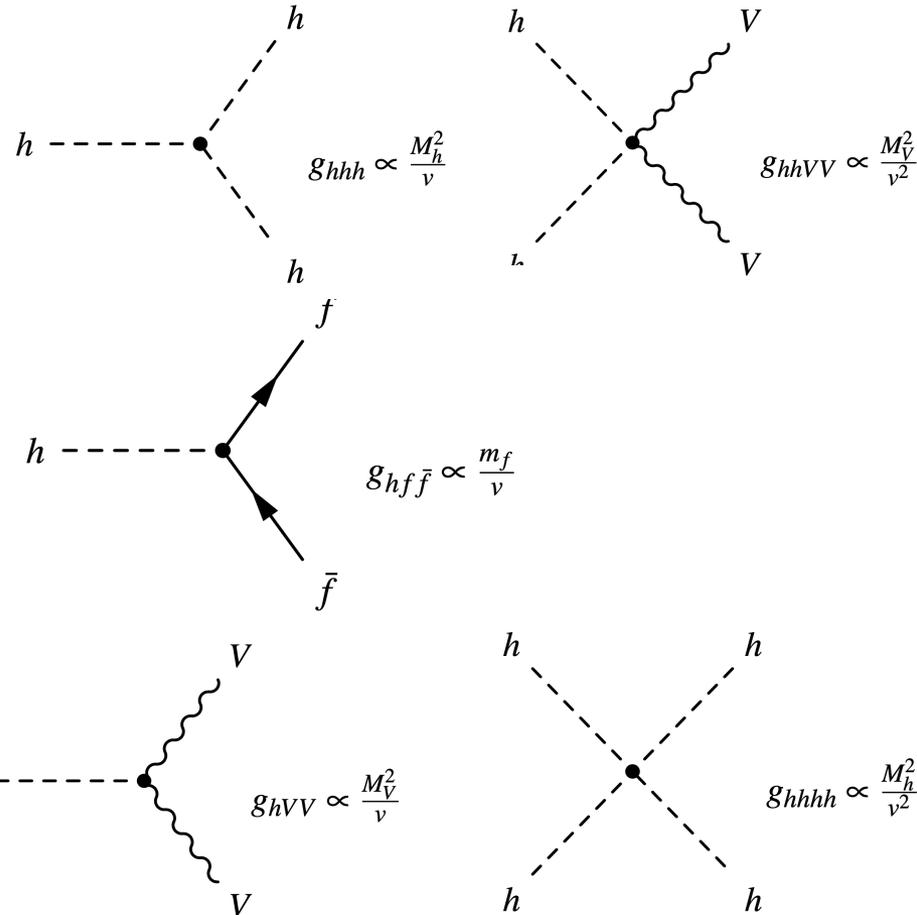

$$g_{hVV} \propto \frac{M_V^2}{v} \quad g_{hhVV} \propto \frac{M_V^2}{v^2}$$

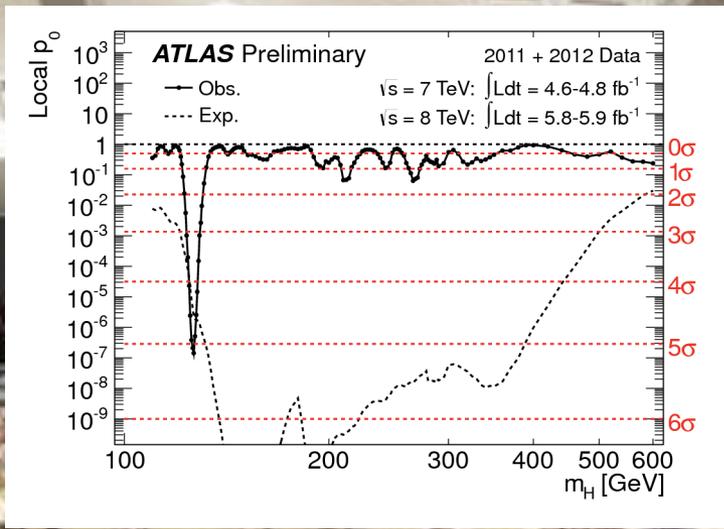

- Yukawa couplings to fermions

$$g_{hf\bar{f}} \propto \frac{m_f}{v}$$

- Self-couplings

$$g_{hhh} \propto \frac{M_h^2}{v} \quad g_{hhhh} \propto \frac{M_h^2}{v^2}$$

# The Long Way to Discovery

# A PHENOMENOLOGICAL PROFILE OF THE HIGGS BOSON

John ELLIS, Mary K. GAILLARD \* and D.V. NANOPOULOS \*\*  
*CERN, Geneva*

Received 7 November 1975

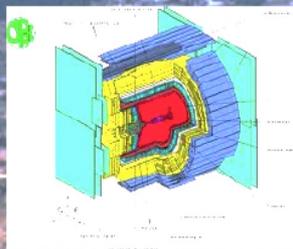

We should perhaps finish with an apology and a caution. We apologize to experimentalists for having no idea what is the mass of the Higgs boson, unlike the case with charm <sup>3),4)</sup> and for not being sure of its couplings to other particles, except that they are probably all very small. For these reasons we do not want to encourage big experimental searches for the Higgs boson, but we do feel that people performing experiments vulnerable to the Higgs boson should know how it may turn up.

Electron-positron collider up to  $s^{1/2} = 209$  GeV

FIT

Backgrounds +

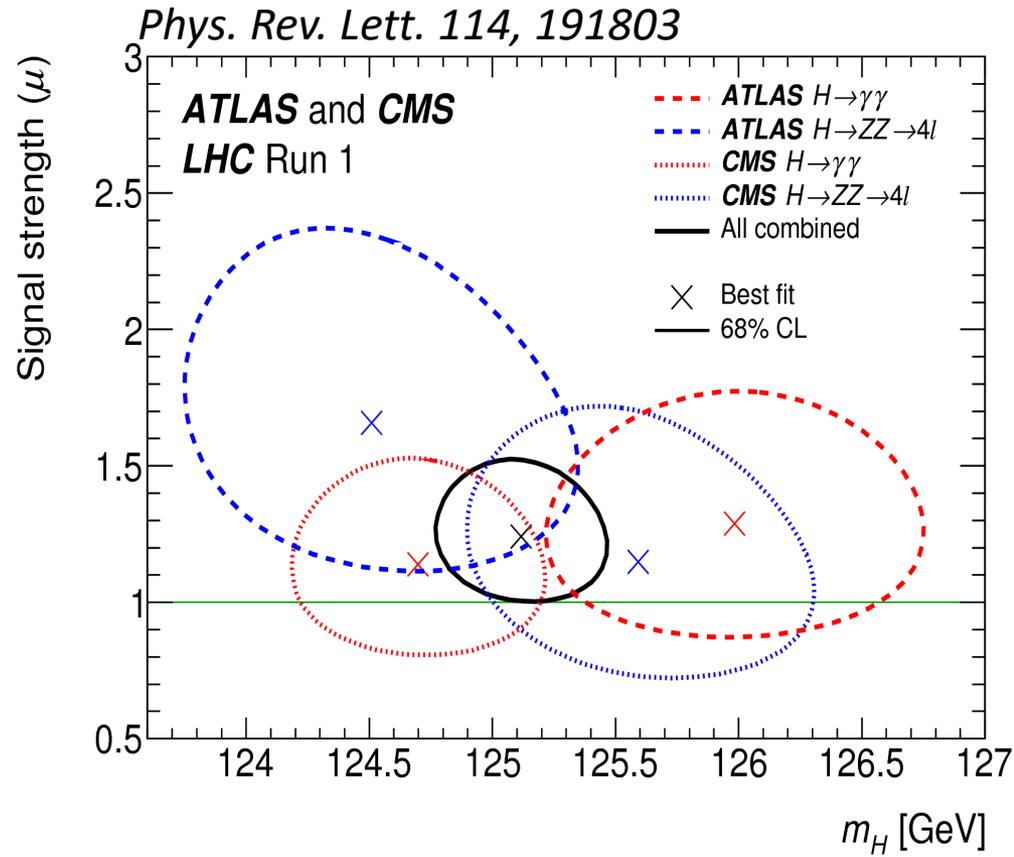

# Signal strength measurements

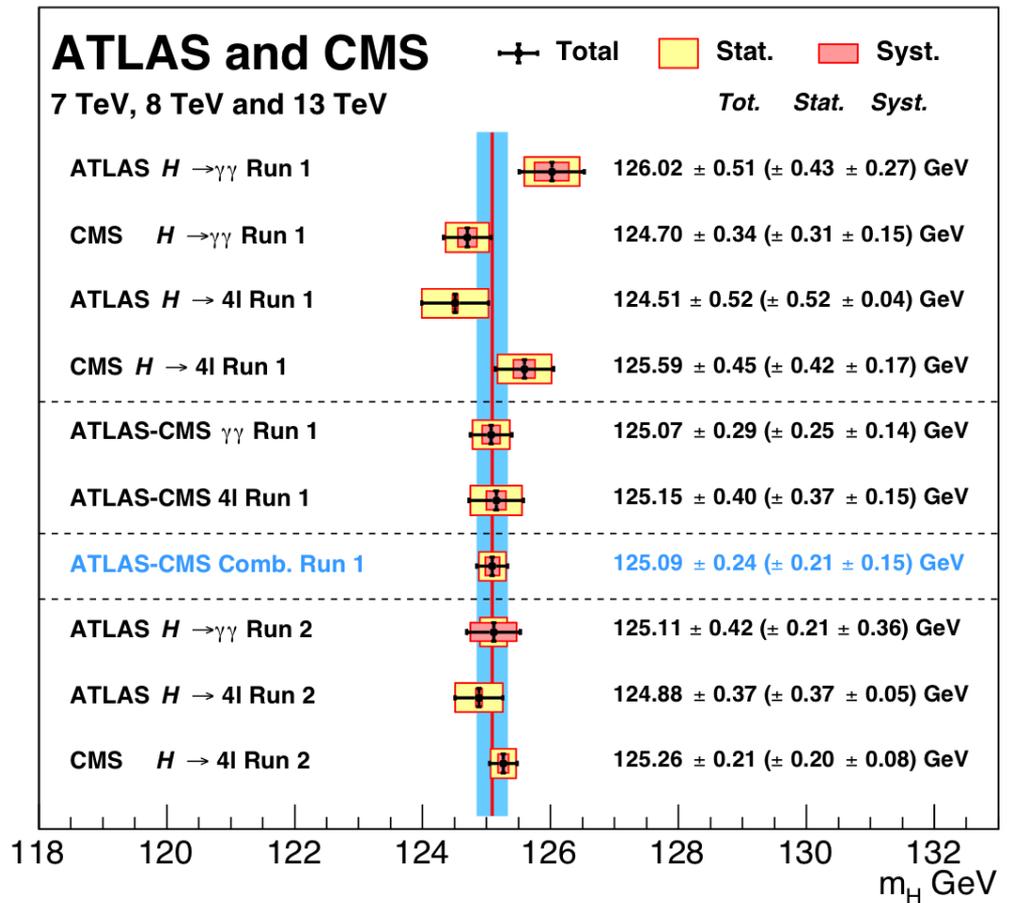

# Higgs boson mass

- Mass: around 125 GeV  
**Was the only unknown SM parameter** 😊
- For a while, different mass values were being measured in ATLAS and CMS, and in different channels
- Numbers evolved with accumulated statistics

# Higgs boson mass

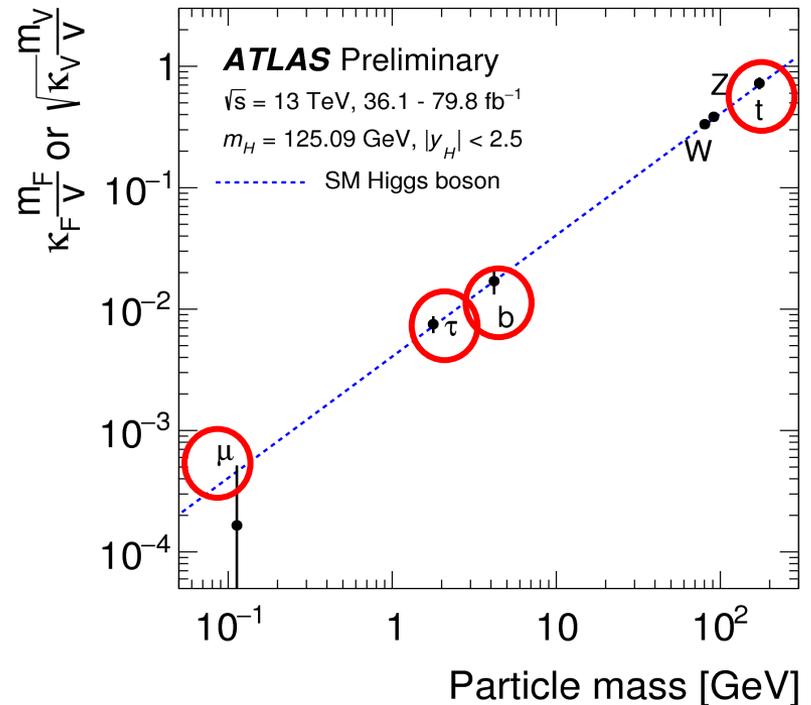

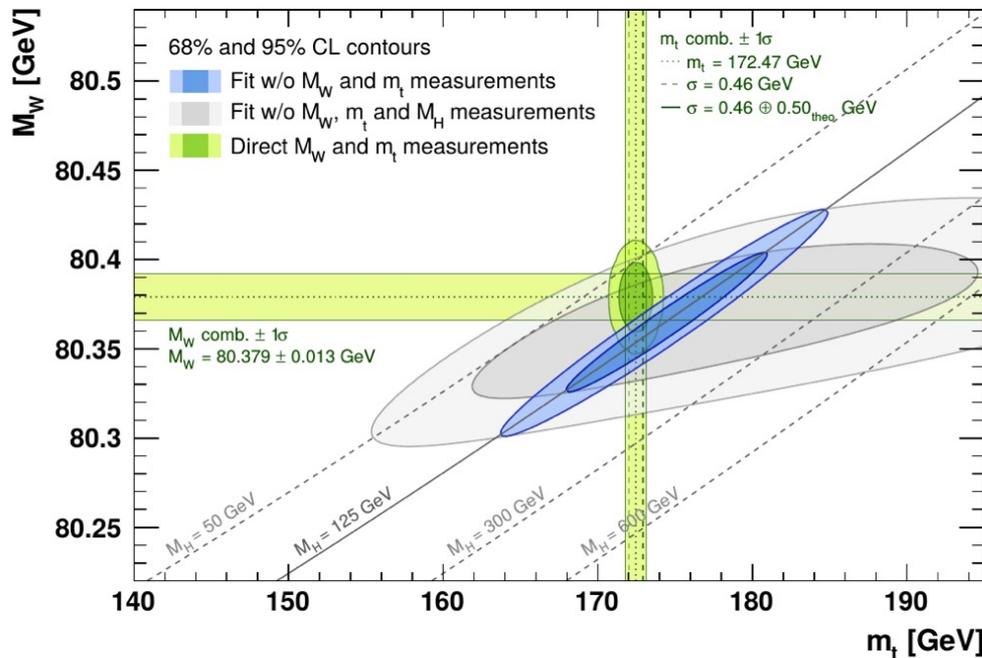

- Mass measurement from
  - $H \rightarrow ZZ^* \rightarrow 4l$
  - $H \rightarrow \gamma\gamma$
- Precision at the permille level achieved

# Exploring the electroweak scale

- Precision measurements of  $m_W$ ,  $m_t$ ,  $m_H$  are stringent tests of the SM at the EW scale
  - E.g. excluding measured  $m_H$ , global EW fit gives  $m_H = 90 \pm 21$  GeV (1.7  $\sigma$  tension) driven in part by  $m_{\text{top}}$

arXiv:1803.01853

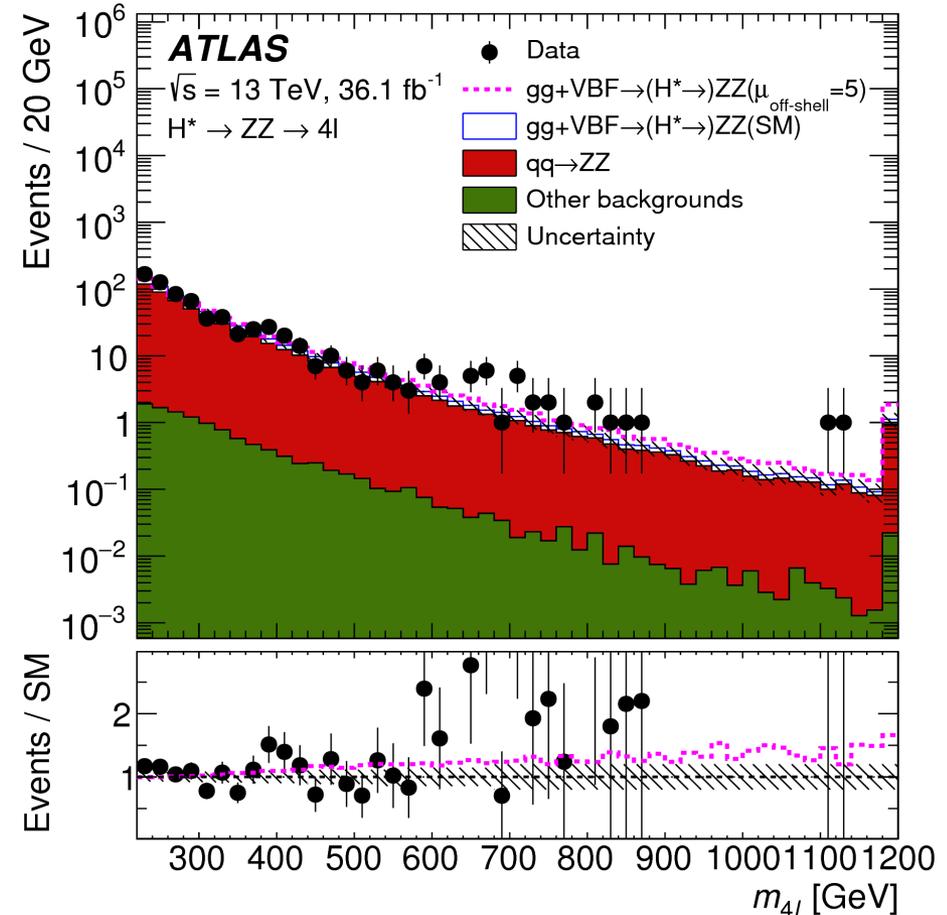

# Higgs boson width

- SM Higgs width  $\Gamma_H \sim 4.1$  MeV
  - Too small to be measured directly
  - Best direct limit from CMS:
    - $\Gamma_H < 1.1$  GeV @ 95% CL
- Off-shell Higgs production sensitive(\*) to  $\Gamma_H$

$$\frac{\mu_{\text{off-shell}}}{\mu_{\text{on-shell}}} = \frac{\kappa_{g,\text{off-shell}}^2 \cdot \kappa_{Z,\text{off-shell}}^2}{\kappa_{g,\text{on-shell}}^2 \cdot \kappa_{Z,\text{on-shell}}^2} \frac{\Gamma_H}{\Gamma_H^{SM}}$$

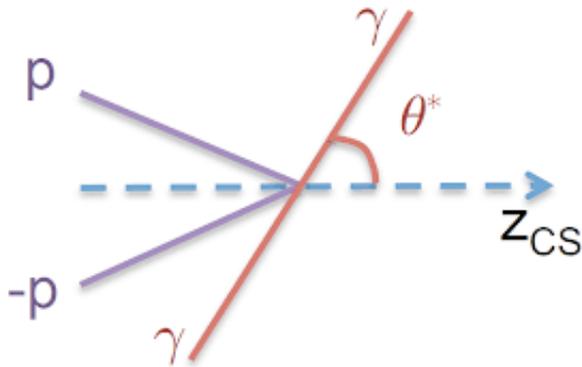

- ATLAS measurement:
  - $pp \rightarrow H \rightarrow ZZ \rightarrow 4l$  and  $ZZ \rightarrow 2l2\nu$
  - $m(H) > 2 m(Z)$
  - 36.1 fb<sup>-1</sup> of 13 TeV data
  - Observed (expected) limit:
    - $\Gamma_H < 14.4$  (15.2) MeV

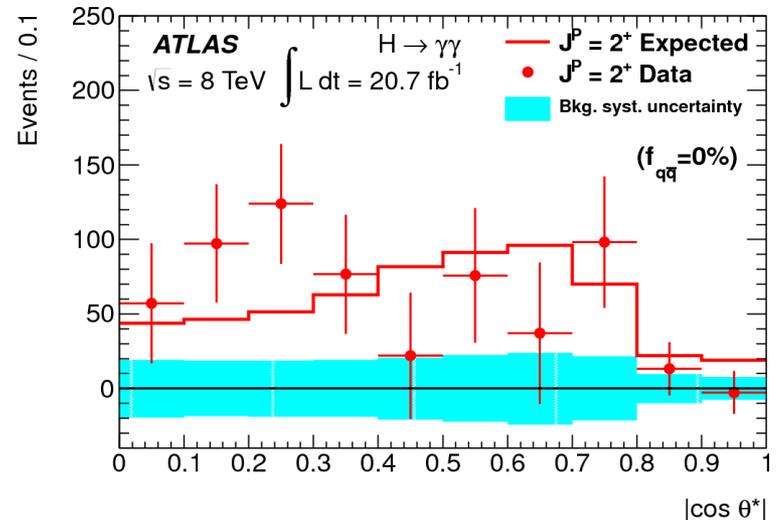

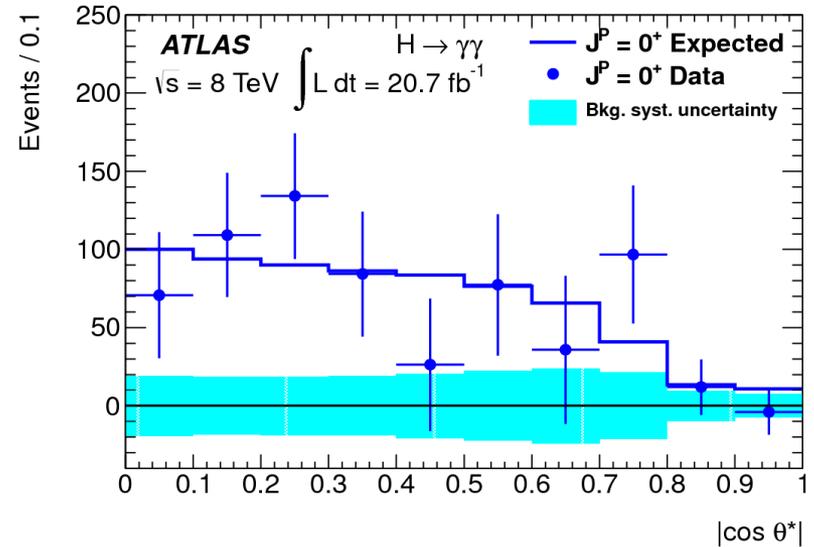

(\*) Assume interference term with  $gg \rightarrow ZZ$  proportional to  $K_{g,\text{off-shell}} \cdot K_{Z,\text{off-shell}}$

# Measuring the Higgs Spin

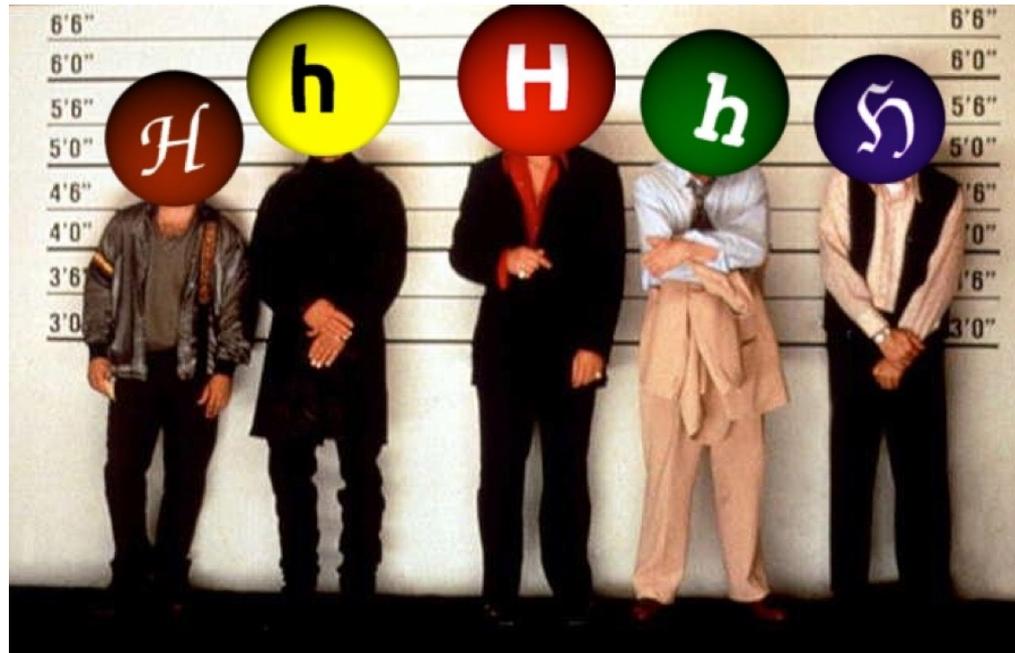

- Polar angle  $\theta$  in the rest frame of the diphoton system (Collins-Soper frame)

$$|\cos \Theta^*| = \frac{|\sinh(\Delta\eta^{\gamma\gamma})|}{\sqrt{1 + \frac{p_{T,\gamma\gamma}^2}{m_{\gamma\gamma}^2}}} \frac{2p_T^{\gamma_1} p_T^{\gamma_2}}{m_{\gamma\gamma}^2}$$

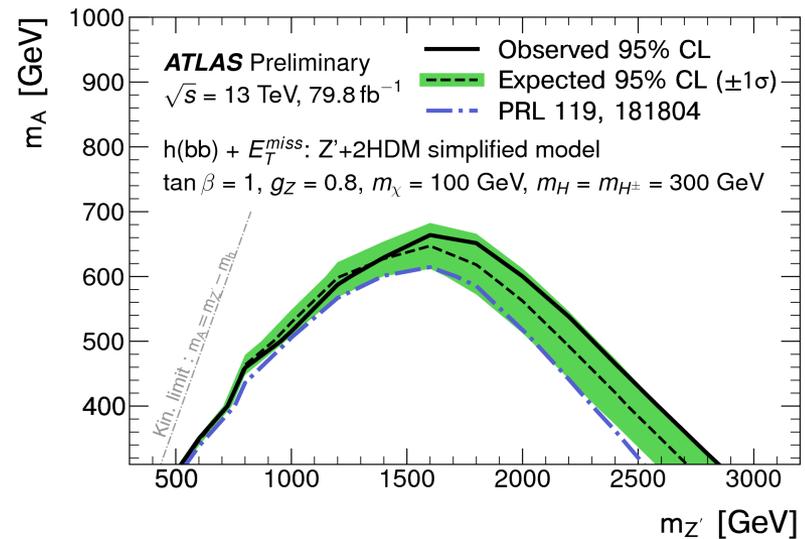

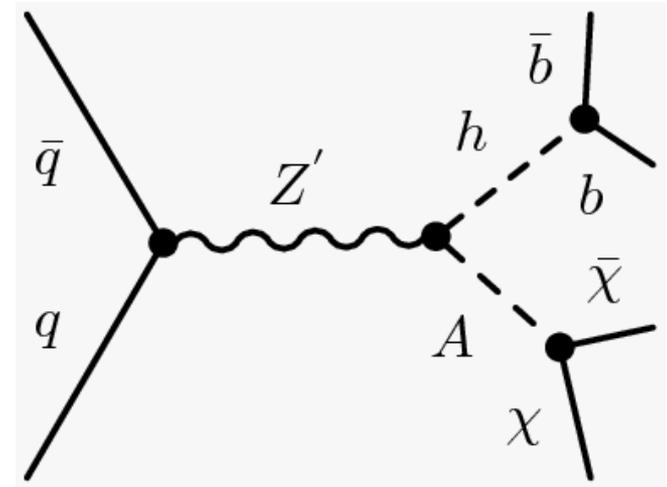

# Casting a wider net

# Higgs + Dark Matter

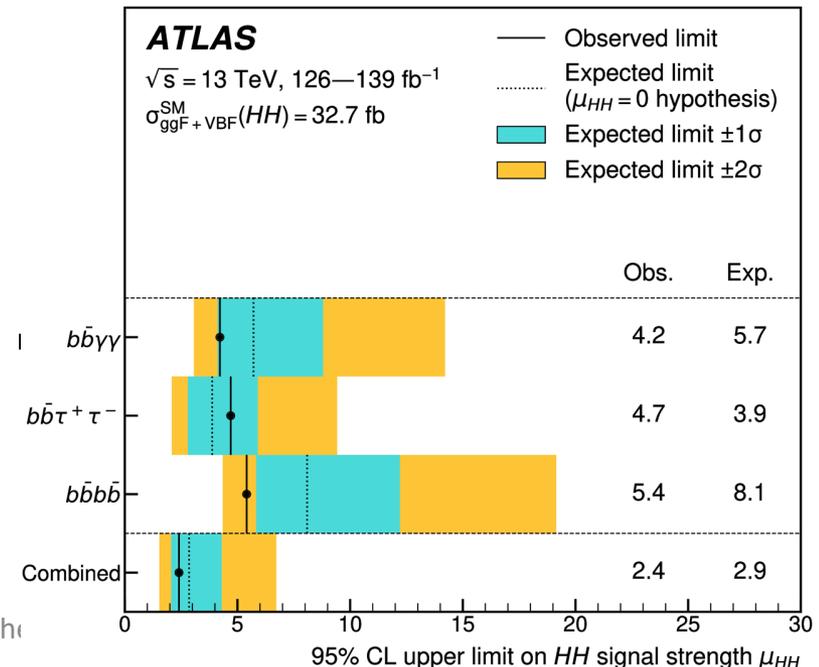

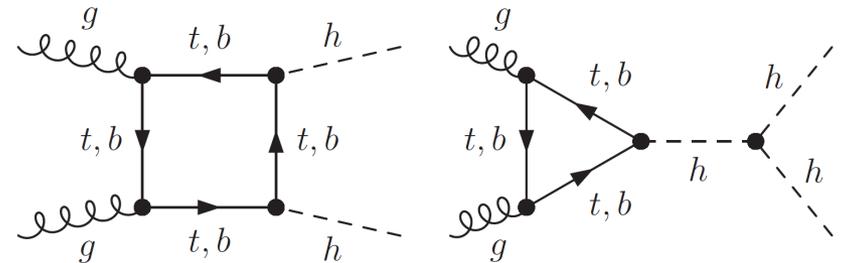

- Used  $79.8 \text{ fb}^{-1}$  of 13 TeV data
  - High  $E_T^{\text{miss}}$  ( $>150 \text{ GeV}$ ) and b-tagging to suppress backgrounds
  - Reconstruct b-jets as 2 small jets or merged variable-radius (VR) track jets
- Signal benchmark: Type-II 2HDM +  $U(1)_{Z'}$  symmetry (Z'-2HDM)
- Main backgrounds:  $t\bar{t}$ , W/Z+jets
- Excluded region in  $m_A - m_{Z'}$  plane

# Triple Higgs coupling

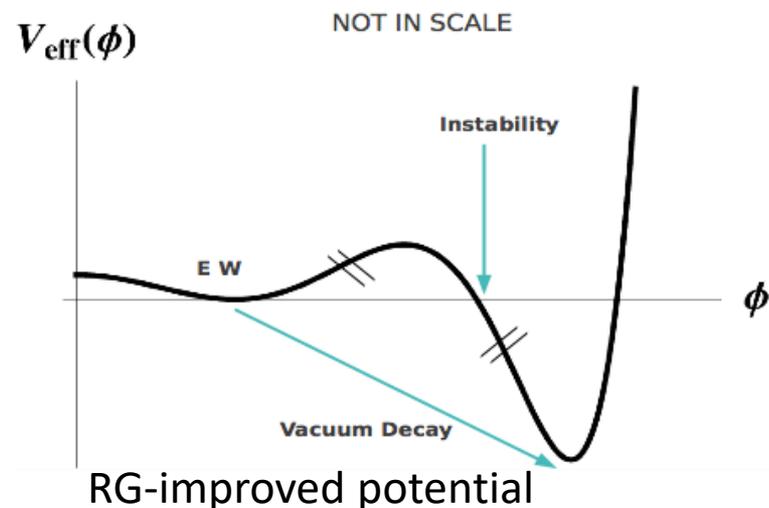

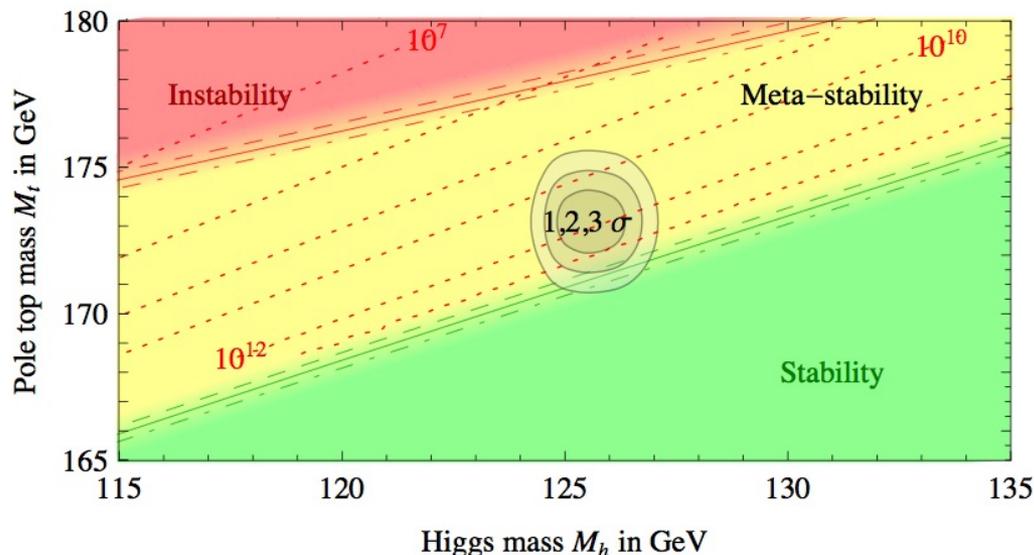

- The triple Higgs coupling  $\lambda_{HHH}$  can be probed through di-Higgs production
- Very suppressed in SM!
  - Negative interference between LO diagrams
  - Cross section 1500x less than ggF
- Wide range of decay BR and channel purity
- Combination: at  $\approx 2.5 \times$  SM sensitivity – with  $\approx 5\%$  of the HL-LHC luminosity analyzed

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

Di-Higgs combination plot [here](#)

# A bit of fun...

- What if...
  - At higher orders, Higgs potential doesn't have to be stable
  - Depending on  $m_t$  and  $m_H$  second minimum can be lower than EW minimum  $\Rightarrow$  tunneling between EW vacuum and true vacuum?!
- “For a narrow band of values of the top quark and Higgs boson masses, the Standard Model Higgs potential develops a shallow local minimum at energies of about  $10^{16}$  GeV, where primordial inflation could have started in a cold metastable state”, I. Masina, arXiv:1403.5244 [astro-ph.CO]

2022: ttH, H->bb fiducial cross section  
2022: Preliminary results for CP of ttH coupling studied in ttH, H->bb

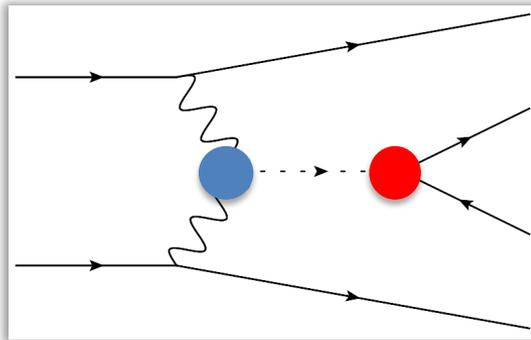

# ttH CP measurement

- Sakharov conditions for a matter-dominated universe require CP violation
- Known CP-violating processes:
  - From complex phases in CKM-matrix - quark mixing
  - Maybe in PNMS-matrix as well - neutrino mixing
- BUT: insufficient, by orders of magnitude
- CP violation in Higgs sector?
  - Possible in some models with extended Higgs sector (e.g. some 2HDMs)
  - Need **mixing** of scalar (CP-even) and pseudo-scalar (CP-odd) Higgs states
- What do we know about Higgs CP properties?
  - In the SM, Higgs scalar is a CP eigenstate with  $J^{CP} = 0^{++}$
  - Pure  $J^P = 0^-$  hypothesis for observed Higgs boson was ruled out in Run 1
  - But a **large** CP-odd admixture is not ruled out

# How to search for a CP-odd admixture?

- Effect of CP-odd components on **bosonic couplings** parametrized as expansion with higher order terms suppressed by powers of scale of new physics  $\Lambda$
- Could explain why a CP-odd admixture has not been seen

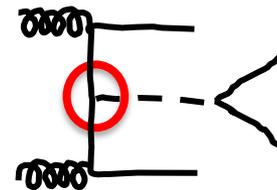

- **Fermionic couplings** are affected at tree level
- Mixing angle  $\alpha$  between CP-even and CP-odd coupling components
- More notable for heavier fermions due to enhanced coupling

$$\mathcal{L}_{VVH} = \mathcal{L}_{VVH,SM} + \frac{1}{\Lambda^2} c \phi \tilde{V}_{\mu\nu} V^{\mu\nu} + \dots$$

$$\mathcal{L}_{ffH} = \kappa'_f y_f \phi \bar{\psi}_f (\cos \alpha + i \gamma_5 \sin \alpha) \psi_f$$

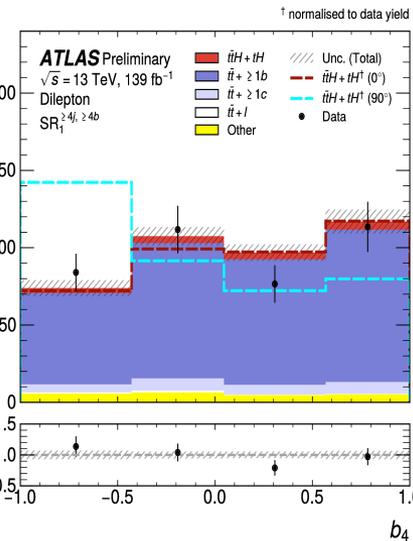

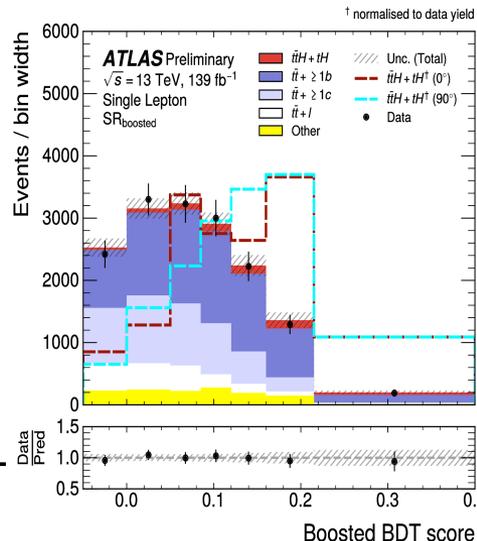

# H-top Coupling in ttH/tH production

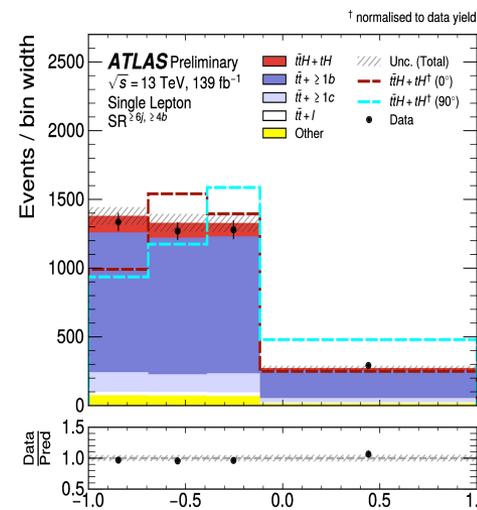

- Calculate CP-sensitive observables  $b_2$  and  $b_4$  from top-quark 3-momenta
- Use different observables in combined fit depending on region

$$b_2 = \frac{(\vec{p}_1 \times \hat{n}) \cdot (\vec{p}_2 \times \hat{n})}{|\vec{p}_1| |\vec{p}_2|}$$

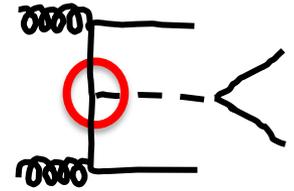

$$b_4 = \frac{p_1^z p_2^z}{|\vec{p}_1| |\vec{p}_2|}$$

# Outlook

- What is the Higgs boson and what is it good for?
- How did we find it?
- Why do we care?
- And what comes next?

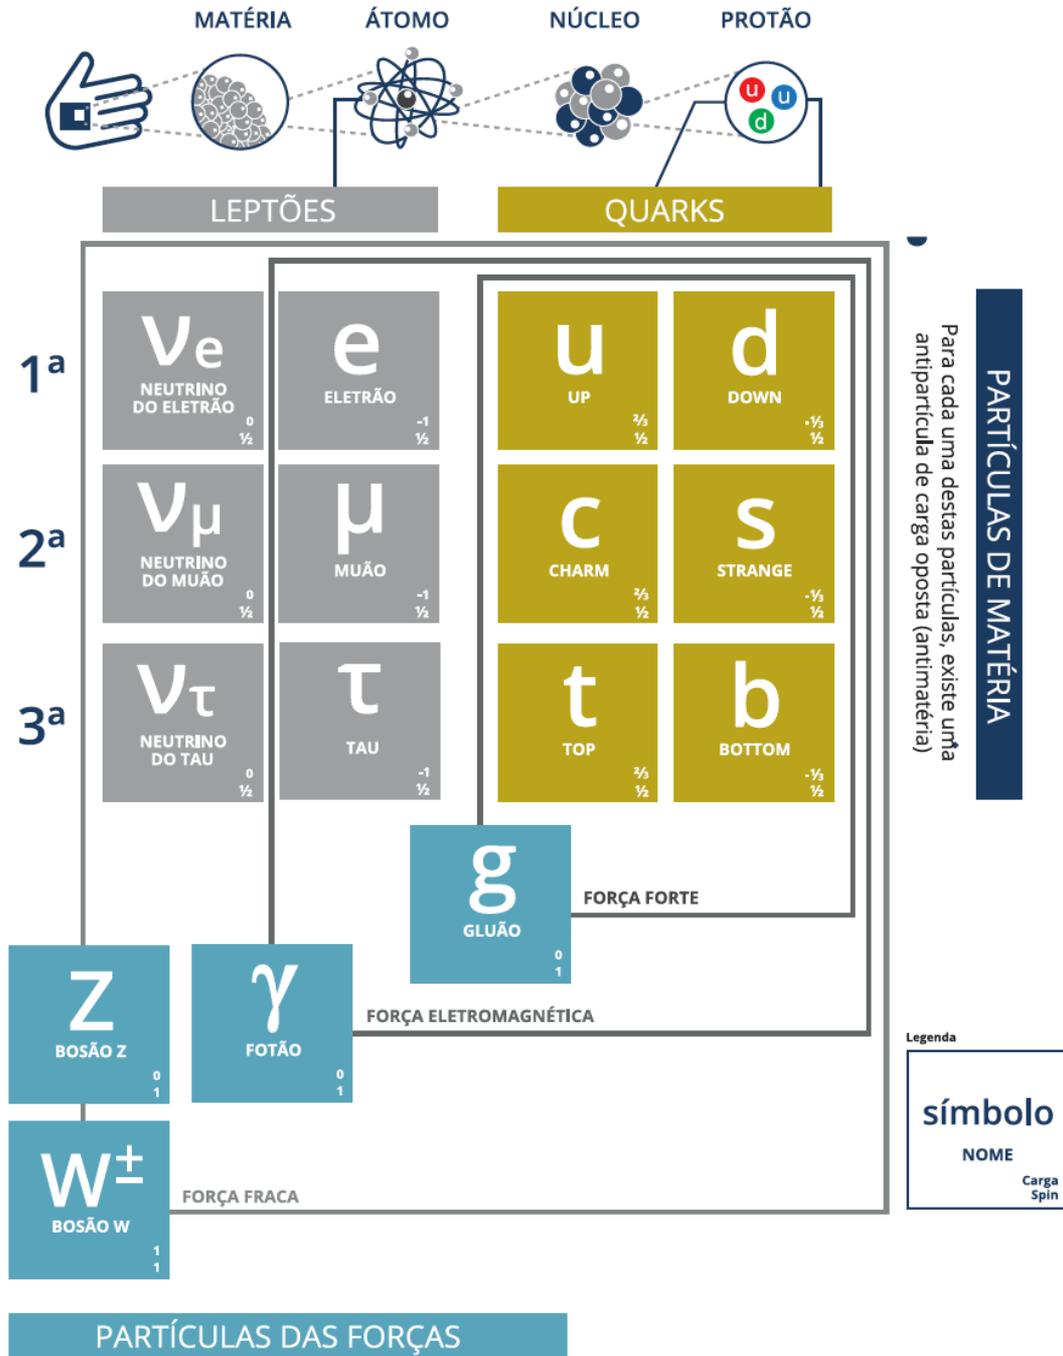

# Introduction

The Standard Model particles and interactions, and some theory to set the scene...

# Fundamental particles and forces

- Electromagnetic:
  - Carried by photons
  - Acts on electrical charge
- Weak:
  - Carried by:
    - $W^\pm$  (charged current)
    - $Z^0$  (neutral current)
  - Acts on weak isospin
- Strong:
  - Carried by 8 gluons
  - Acts on colour

# Lagrangians, symmetries and all that

Leonhard Euler(1707–1783)

Emmy Noether (1882 – 1935)

Joseph-Louis Lagrange (1736–1813)

# Lagrangians in classical mechanics

The equations of motion of a system are derived from a scalar **Lagrangian** function of **generalized coordinates** and **velocities** (time derivatives of the coordinates)

$$L(q, \dot{q}) = T - V$$

From minimizing the action  $S$ , get the **Euler-Lagrange equations**:

$$S = \int dt L(q_i, \dot{q}_i) \quad \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0$$

For a point particle in a potential  $U$ , with  $q_i = x, y, z$

$$L = \frac{1}{2} m \dot{q}_i^2 - U(q_i) \quad \frac{d}{dt} (m \dot{q}_i) + \frac{\partial U}{\partial q_i} = 0 \quad m \ddot{q}_i = - \frac{\partial U}{\partial q_i}$$

# Symmetries and conservation laws

Noether's theorem:

If a system has a continuous symmetry property, then there are corresponding quantities whose values are conserved in time.

Simplest case:

Coordinates not explicitly appearing in the Lagrangian =>  
Lagrangian invariant over a transformation of these coordinates

Example: point mass  $m$  orbiting in the field of a fixed mass  $M$

$$L(r, \phi, \dot{r}, \dot{\phi}) = T - V = \frac{1}{2}m\dot{r}^2 + \frac{1}{2}mr^2\dot{\phi}^2 + \frac{GMm}{r}$$

Since the lagrangian doesn't depend explicitly on  $\phi$  (symmetry with respect to rotations in space), the Euler-Lagrange equation gives

$$\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\phi}} \right) = 0 \Leftrightarrow \frac{\partial L}{\partial \dot{\phi}} = mr^2\dot{\phi} = J$$

Where the angular momentum  $J$  is a constant of motion!

# Let's go to quantum fields...

$$\frac{1}{\sqrt{2}}|\text{cat}\rangle + \frac{1}{\sqrt{2}}|\text{cat}\rangle$$

Richard Feynman  
(1918 - 1988)

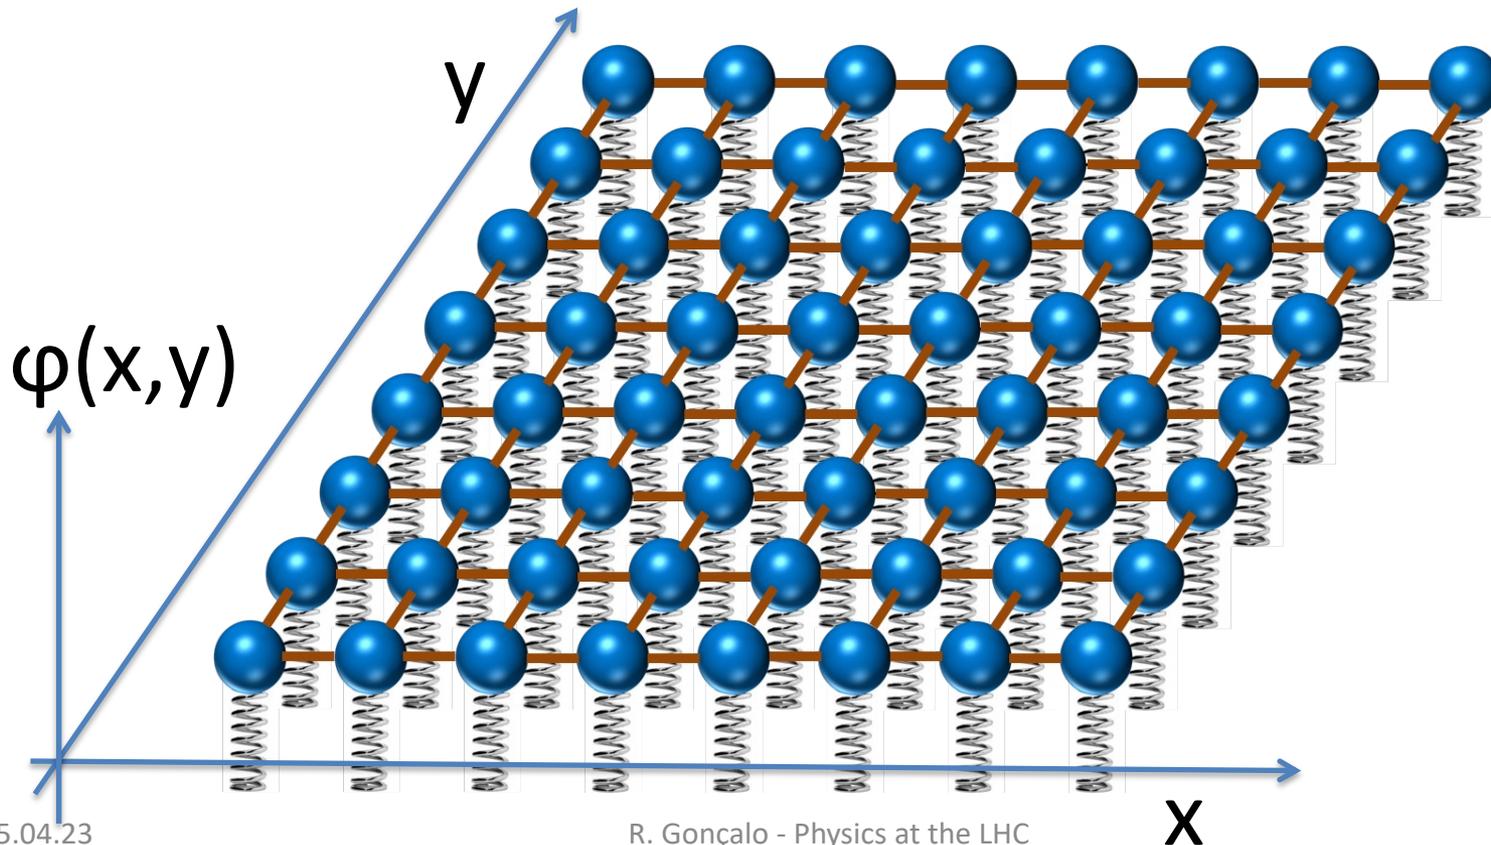

Fluffy (?-?)

Erwin  
Schrödinger  
(1887 - 1961)

# Now in quantum field theory...

Imagine space as an infinite continuum of balls and springs, where each ball is connected to its neighbours by elastic bands. **Particles are perturbations of this field**

Generalized coordinates are now **fields** (dislocation of each spring)

$$q_i \rightarrow \phi_i(x^\mu)$$

In a relativistic theory we must treat space and time coordinates on an equal footing, so the derivatives in the classical equations are now

$$\frac{d}{dt}, \nabla \rightarrow \partial_\mu = \left( \frac{\partial}{\partial t}, \frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z} \right)$$

In place of a Lagrangian we have a **Lagrangian density** (we call it Lagrangian anyway, just to be confusing)

$$L(q_i, \frac{dq_i}{dt}) \rightarrow \mathcal{L}(\phi_i, \partial_\mu \phi_i) \quad \text{with: } L = \int \mathcal{L} d^3 \mathbf{x}$$

The new Euler-Lagrange equation now becomes

$$\partial_\mu \left( \frac{\partial \mathcal{L}}{\partial (\partial_\mu \phi_i)} \right) - \frac{\partial \mathcal{L}}{\partial \phi_i} = 0$$

- Example Lagrangians and equations of motion:
- Klein-Gordon Lagrangian for spin 0 particles (scalars):

$$\mathcal{L}_{KG} = \frac{1}{2}(\partial_\mu \phi)(\partial^\mu \phi) - \frac{1}{2}m^2 \phi^2$$

$$\partial_\mu \partial^\mu \phi + m^2 \phi = 0$$

- Dirac Lagrangian for spin 1/2 particles (fermions):

$$\mathcal{L}_D = i\bar{\psi}\gamma^\mu \partial_\mu \psi - m\bar{\psi}\psi$$

$$i\gamma^\mu \partial_\mu \psi - m\psi = 0$$

- Proca Lagrangian for spin 1 (vector) particles:

$$\mathcal{L}_P = \frac{-1}{16\pi}(\partial^\mu A^\nu - \partial^\nu A^\mu)(\partial_\mu A_\nu - \partial_\nu A_\mu) + \frac{1}{8\pi}m^2 A^\nu A_\nu$$

$$\partial_\mu(\partial^\mu A^\nu - \partial^\nu A^\mu) + m^2 A^\nu = 0$$

- Important:

Mass terms in Lagrangian are quadratic in the fields

# Global gauge invariance

Take the Dirac Lagrangian for a spinor field  $\psi$  representing a spin- $\frac{1}{2}$  particle, for example an electron:

$$\mathcal{L} = i\hbar\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi$$

It is invariant under a global U(1) phase transformation like:

$$\psi(x) \rightarrow \psi'(x) = e^{iq\chi}\psi(x)$$

Where  $\chi$  is a constant

$$\mathcal{L}' = e^{-iq\chi}e^{iq\chi}(i\hbar\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi) = \mathcal{L}$$

Note: gauge invariance of the Dirac equation can be demonstrated to lead to conservation of probability current  $j^\mu$

$$j^\mu = (\rho, \mathbf{J}) = \bar{\psi}\gamma^\mu\psi$$

# Local gauge invariance and interactions

If  $\chi = \chi(x)$  then we get extra terms in the Lagrangian:

$$\begin{aligned}\mathcal{L}' &= ie^{-iq\chi}\bar{\psi}\gamma^\mu[e^{iq\chi}\partial_\mu\psi + iq(\partial_\mu\chi)e^{iq\chi}\psi] - me^{-iq\chi}e^{iq\chi}\bar{\psi}\psi \\ &= \mathcal{L} - q\bar{\psi}\gamma^\mu(\partial_\mu\chi)\psi\end{aligned}$$

But we can now make the Lagrangian invariant by adding an **interaction term** with a new **gauge field**  $\mathbf{A}_\mu$  which transforms as:

$$A_\mu \rightarrow A'_\mu = A_\mu - \partial_\mu\chi$$

We get:

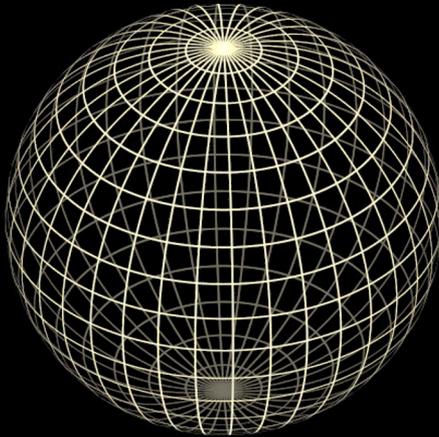

$$\mathcal{L} = i\bar{\psi}\gamma^\mu\partial_\mu\psi - m\bar{\psi}\psi - q\bar{\psi}\gamma^\mu A_\mu\psi$$

Note:

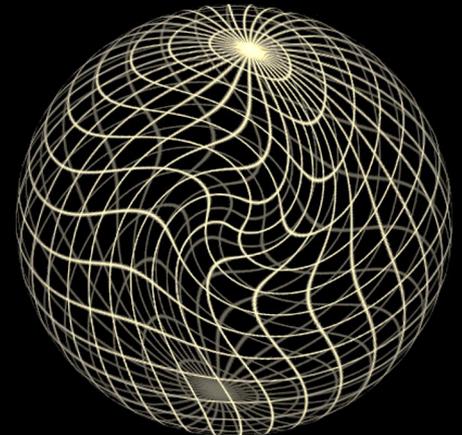

1. The new gauge field  $A_\mu$  is the photon in QED
2. The mass of the fermion is the coefficient of the term on  $\bar{\psi}\psi$
3. There is no term in  $A_\mu A^\mu$  (the photon has zero mass)

$$\psi(x) \rightarrow \psi'(x) = e^{iq\chi} \psi(x)$$

Original sphere

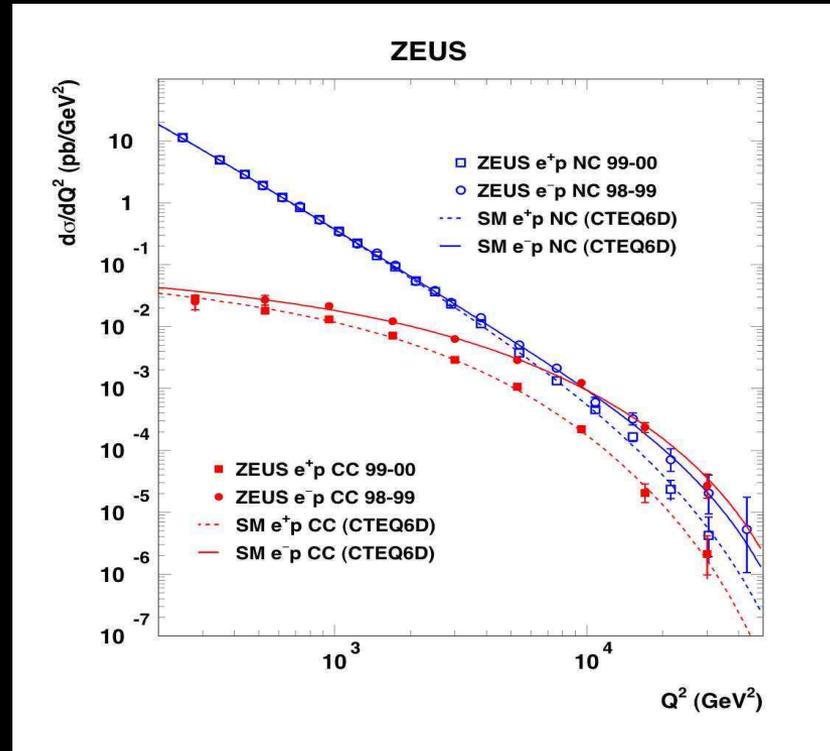

Local transformação

$\chi = \text{constant}$

$\chi = \chi(x)$

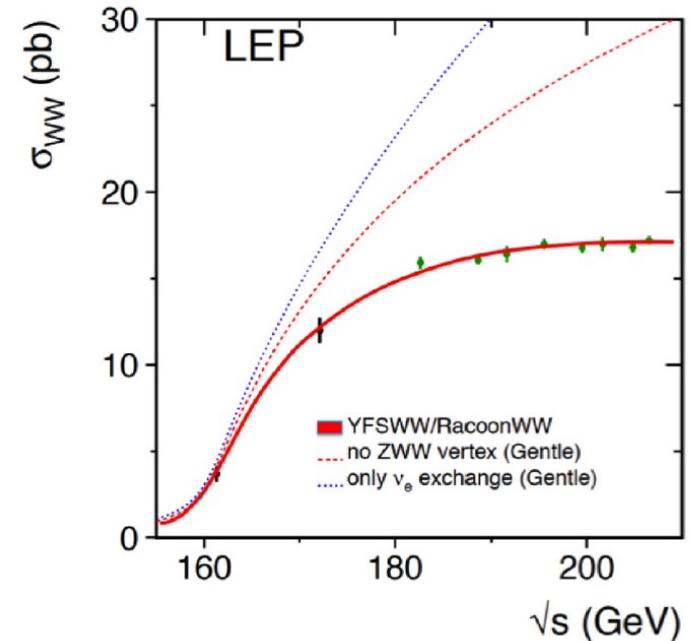

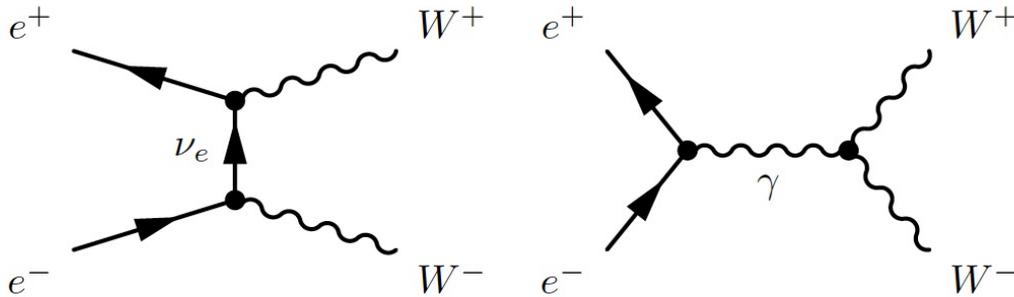

# Weak Neutral Currents and Electroweak Unification

# Electroweak Unification

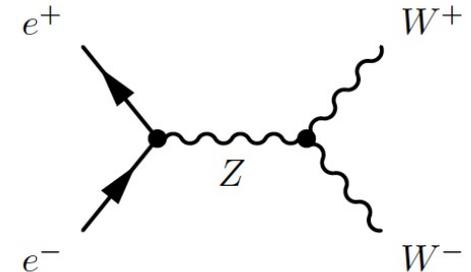

- Weak CC interactions explained by  $W^\pm$  boson exchange
- $W^\pm$  bosons are charged, thus they couple to the  $\gamma$

Consider  $e^-e^+ \rightarrow W^+W^-$ : 2 diagrams (+interference)

- Cross-section **diverges** at high energy
- Divergence cured by introducing  $Z$  boson
- Extra diagram for  $e^-e^+ \rightarrow W^+W^-$
- Idea only works if  $\gamma$ ,  $W^\pm$ ,  $Z$  couplings are related

$\Rightarrow$  **Electroweak Unification**

# Sheldon Glashow's “stumbling block”

## PARTIAL-SYMMETRIES OF WEAK INTERACTIONS

SHELDON L. GLASHOW †

*Institute for Theoretical Physics, University of Copenhagen, Copenhagen, Denmark*

Received 9 September 1960

**Abstract:** Weak and electromagnetic interactions of the leptons are examined under the hypothesis that the weak interactions are mediated by vector bosons. With only an isotopic triplet of leptons coupled to a triplet of vector bosons (two charged decay-intermediaries and the photon) the theory possesses no partial-symmetries. Such symmetries may be established if additional vector bosons or additional leptons are introduced. Since the latter possibility yields a theory disagreeing with experiment, the simplest partially-symmetric model reproducing the observed electromagnetic and weak interactions of leptons requires the existence of at least four vector-boson fields (including the photon). Corresponding partially-conserved quantities suggest leptonic analogues to the conserved quantities associated with strong interactions: strangeness and isobaric spin.

### 1. Introduction

At first sight there may be little or no similarity between electromagnetic effects and the phenomena associated with weak interactions. Yet certain remarkable parallels emerge with the supposition that the weak interactions are mediated by unstable bosons. Both interactions are universal, for only a single coupling constant suffices to describe a wide class of phenomena: both interactions are generated by vectorial Yukawa couplings of spin-one fields ††. Schwinger first suggested the existence of an “isotopic” triplet of vector fields whose universal couplings would generate both the weak interactions and electromagnetism — the two oppositely charged fields mediate weak interactions and the neutral field is light <sup>2</sup>). A certain ambiguity beclouds the self-interactions among the three vector bosons; these can equivalently be interpreted as weak or electromagnetic couplings. The more recent accumulation of experimental evidence supporting the  $\Delta I = \frac{1}{2}$  rule characterizing the non-leptonic decay modes of strange particles indicates a need for at least one additional neutral intermediary <sup>3</sup>).

The mass of the charged intermediaries must be greater than the K-meson mass, but the photon mass is zero — surely this is the principal stumbling block in any pursuit of the analogy between hypothetical vector mesons and photons. It is a stumbling block we must overlook. To say that the decay intermediaries

- There are hints that EM and weak interactions have a common origin
  - Similar gauge structure
  - $W^\pm$  couples to charge
- But there are obvious differences:
  - Different masses of  $W^\pm$ , Z and photon
  - Structure of the vertex is different

# Electroweak Gauge Theory

- Postulate invariance under a gauge transformation like:

$$\psi \rightarrow \psi' = e^{ig\vec{\sigma}\cdot\vec{\Lambda}(\vec{r},t)}\psi$$

an “SU(2)” transformation ( $\sigma$  are 2x2 matrices).

- Operates on the state of “**weak isospin**” – a “rotation” of the isospin state.
- Invariance under SU(2) transformations  $\Rightarrow$  three massless gauge bosons ( $W_1, W_2, W_3$ ) whose couplings are well specified.
- They also have **self-couplings**.

But this doesn't quite work...

Predicts  $W$  and  $Z$  have the same couplings – not seen experimentally!

# Electroweak Gauge Theory

The solution...

- Unify QED and the weak force  $\Rightarrow$  electroweak model
- “SU(2)xU(1)” transformation  
U(1) operates on the “weak hypercharge”  $Y = 2(Q - I_3)$   
SU(2) operates on the state of “weak isospin,  $I$ ”
- Invariance under SU(2)xU(1) transformations  $\Rightarrow$  four massless gauge bosons  $W^+, W^-, W_3, B$
- The two neutral bosons  $W_3$  and  $B$  then **mix** to produce the physical bosons  $Z$  and  $\gamma$
- Photon properties must be the same as QED  $\Rightarrow$  predictions of the couplings of the  $Z$  in terms of those of the  $W$  and  $\gamma$
- Still need to account for the **masses** of the  $W$  and  $Z$ . This is the job of the **Higgs mechanism** (later).

# The GWS Model

The **G**lashow, **W**einberg and **S**alam model treats **EM** and **weak** interactions as different manifestations of a single **unified electroweak** force (Nobel Prize 1979)

Start with 4 massless bosons  $W^+$ ,  $W_3$ ,  $W^-$  and  $B$ . The neutral bosons **mix** to give physical bosons (the particles we see), i.e. the  $W^\pm$ ,  $Z$ , and  $\gamma$ .

$$\begin{pmatrix} W^+ \\ W_3 \\ W^- \end{pmatrix}; B \rightarrow \begin{pmatrix} W^+ \\ Z \\ W^- \end{pmatrix}; \gamma$$

Physical fields:  $W^+$ ,  $Z$ ,  $W^-$  and  $A$  (photon).

$$Z = W_3 \cos \theta_W - B \sin \theta_W$$

$$A = W_3 \sin \theta_W + B \cos \theta_W$$

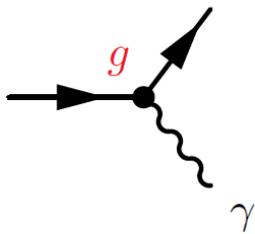

$\theta_W$  Weak Mixing Angle

$W^\pm$ ,  $Z$  “acquire” mass via the **Higgs mechanism**.

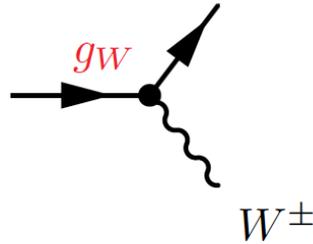

# The GWS Model

The beauty of the **GWS** model is that it makes **exact** predictions of the  $W^\pm$  and  $Z$  masses and of their couplings with **only 3** free parameters.

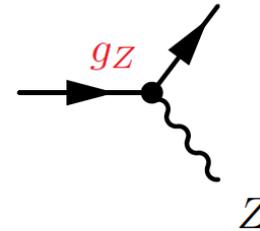

**Couplings given by  $\alpha_{EM}$  and  $\theta_W$**

$$\alpha_{EM} = \frac{e^2}{4\pi} \quad g \sim e$$

$$g_W = \frac{e}{\sin \theta_W}$$

$$g_Z = \frac{e}{\sin \theta_W \cos \theta_W} = \frac{g_W}{\cos \theta_W}$$

**Masses also given by  $G_F$  and  $\theta_W$**

From Fermi theory

$$\frac{G_F}{\sqrt{2}} = \frac{g_W^2}{8m_W^2} = \frac{e^2}{8m_W^2 \sin^2 \theta_W} \quad m_{W^\pm} = \left( \frac{\sqrt{2}e^2}{8G_F \sin^2 \theta_W} \right)^{1/2} \quad m_Z = \frac{m_W}{\cos \theta_W}$$

If we know  $\alpha_{EM}$ ,  $G_F$ ,  $\sin \theta_W$  (from experiment), everything else is defined.

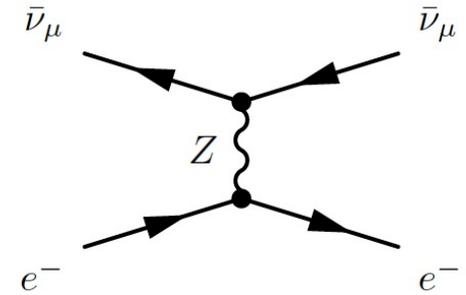

# Evidence for the GWS model

## Problem 1: Mass of elementary particles and gauge bosons

What if we add a photon mass term to the QED Lagrangian?

$$\mathcal{L}_{QED} = \bar{\psi}(i\gamma^\mu \partial_\mu - m_e)\psi - e\bar{\psi}\gamma^\mu\psi A_\mu - \frac{1}{4}F_{\mu\nu}F^{\mu\nu} + \frac{1}{2}m_\gamma A_\mu A^\mu$$

To keep the Lagrangian gauge invariant (against a local U(1) local phase transformation) the photon field transforms as:

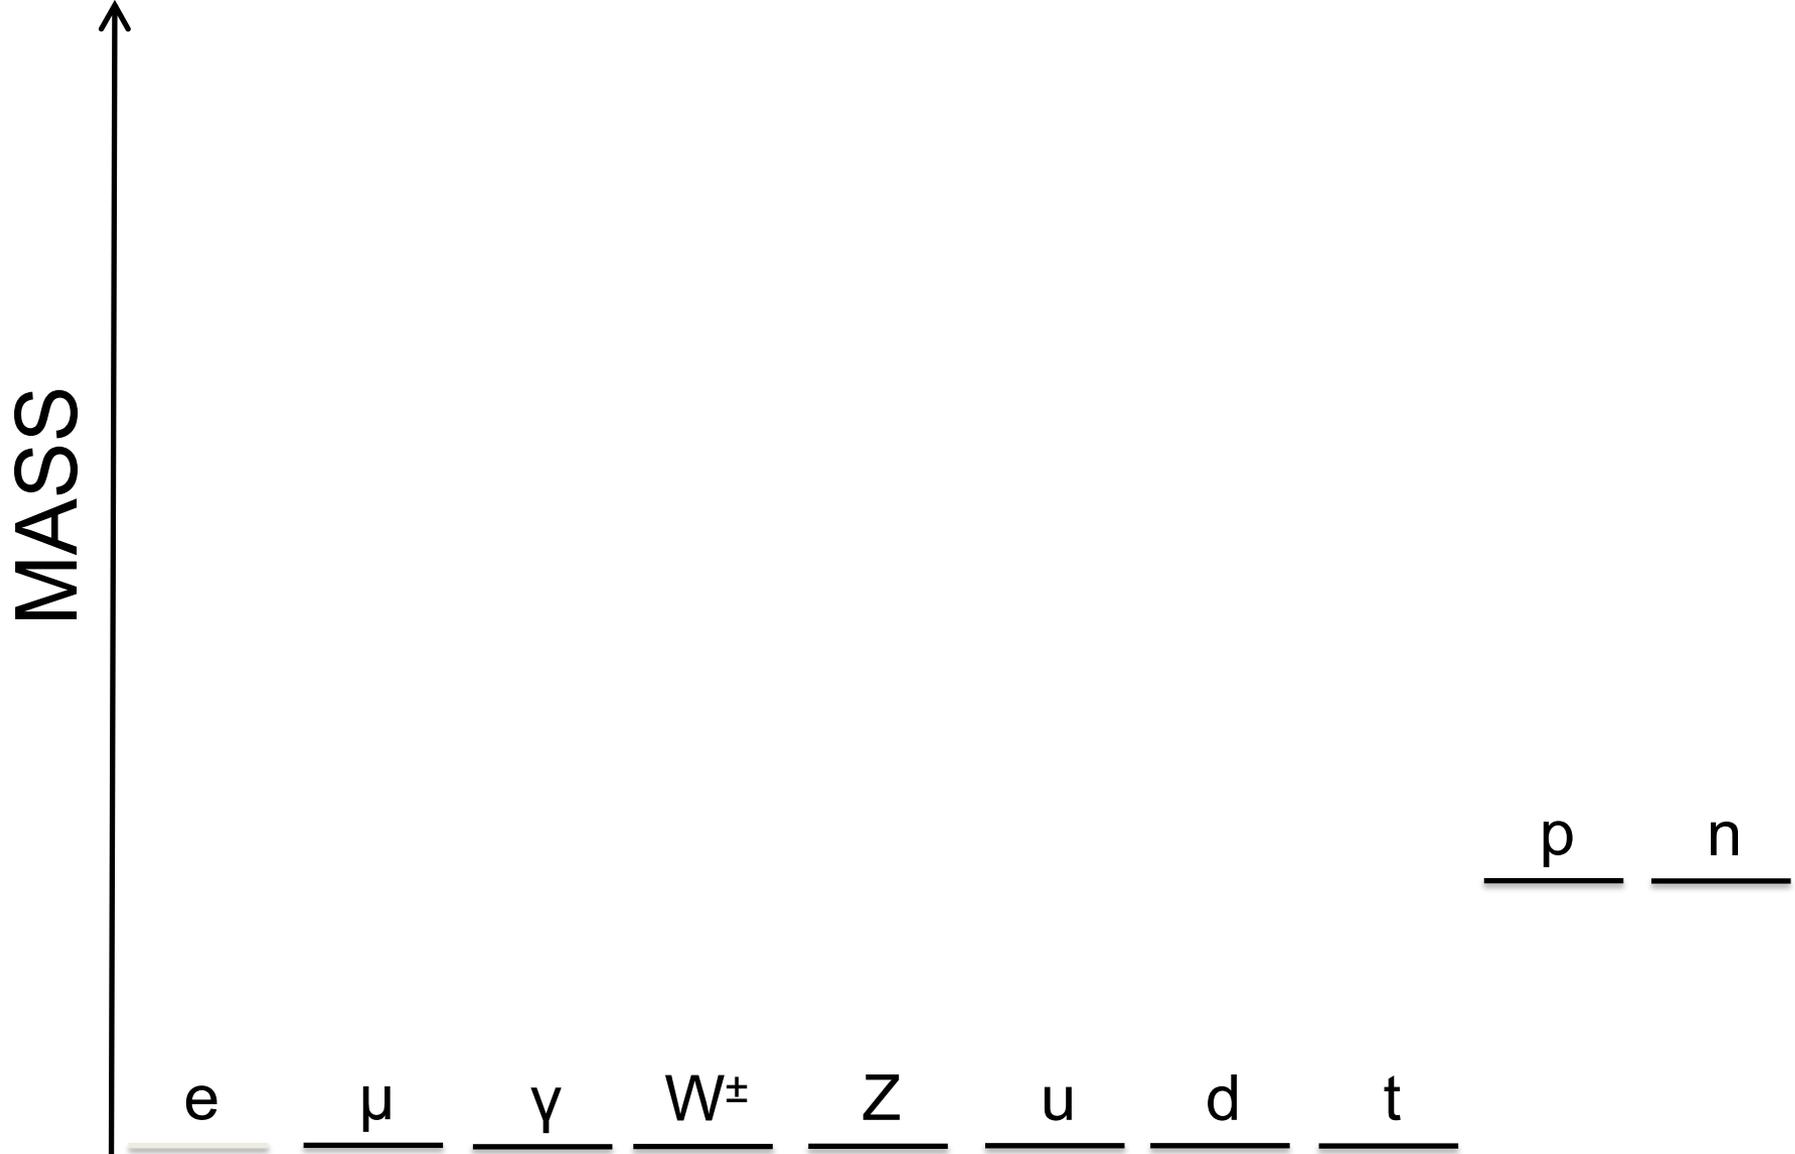

$$A_\mu \rightarrow A'_\mu = A_\mu - \partial_\mu \chi$$

But the  $A^\mu$  mass term breaks the Lagrangian invariance:

$$\frac{1}{2}m_\gamma A_\mu A^\mu \rightarrow \frac{1}{2}m_\gamma (A_\mu - \partial_\mu \chi)(A^\mu - \partial^\mu \chi) \neq \frac{1}{2}m_\gamma A_\mu A^\mu$$

For the  $SU(2)_L$  gauge symmetry transformations of the **weak interaction** the fermion mass term  $m_e\psi\bar{\psi}$  also breaks invariance!

# It should not work...

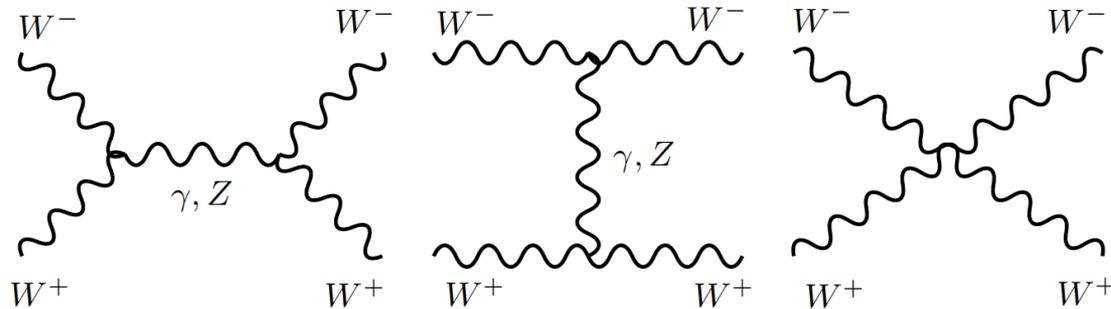

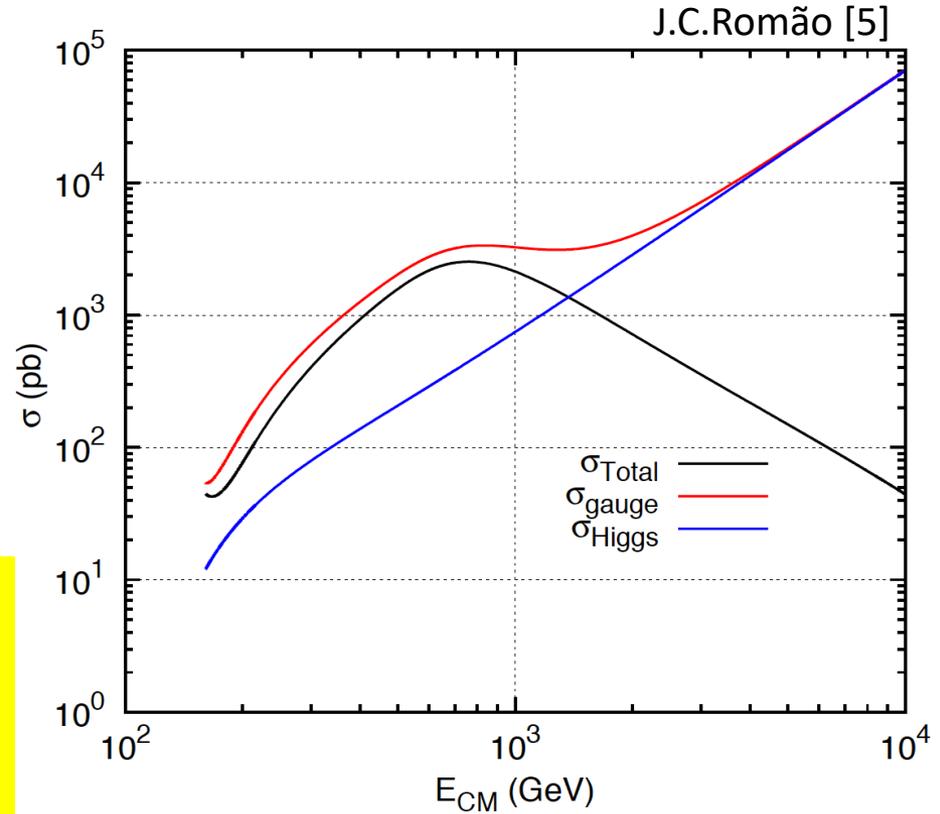

## Problem 2:

### Longitudinal gauge-boson scattering

In the absence of the Higgs, some processes have cross sections that grow with the centre of mass energy of the collision... i.e. breaks unitarity!

The Higgs regulates the cross section through negative interference

**Bottom line: the SM (without the Higgs mechanism) results in wrong calculations and breaks down for massive particles**

Feynman diagrams contributing to longitudinal  $WW$  scattering

# The Higgs Mechanism

Robert Brout (1928 – 2011)

Peter Higgs (b. 1929)

François Englert  
(b. 1932)

- Introduce a SU(2) doublet of spin-0 complex fields

$$\phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} \phi_1 + i\phi_2 \\ \phi_3 + i\phi_4 \end{pmatrix}$$

- New Lagrangian term:

$$\mathcal{L} = (\partial_\mu \phi)^\dagger (\partial^\mu \phi) - V(\phi)$$

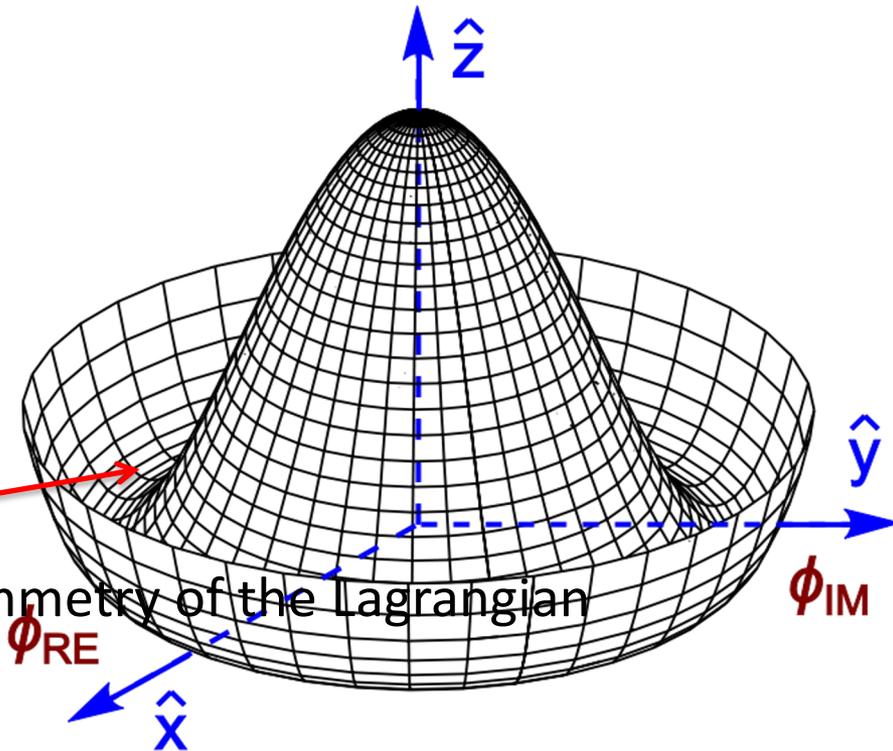

- With a potential

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

- For  $\lambda > 0, \mu^2 > 0$  the potential has a minimum at the origin
- For  $\lambda > 0, \mu^2 < 0$  the potential has an infinite number of minima at:

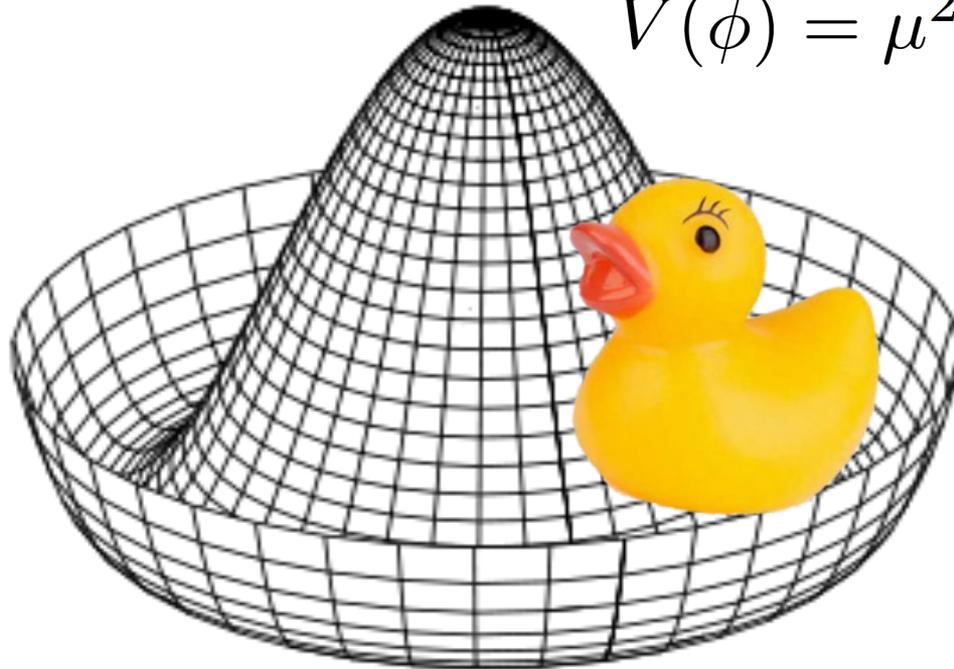

The classical energy state of the field, breaks the symmetry of the Lagrangian

$$|\phi| = \frac{v}{\sqrt{2}} = \sqrt{-\frac{\mu^2}{2\lambda}}$$

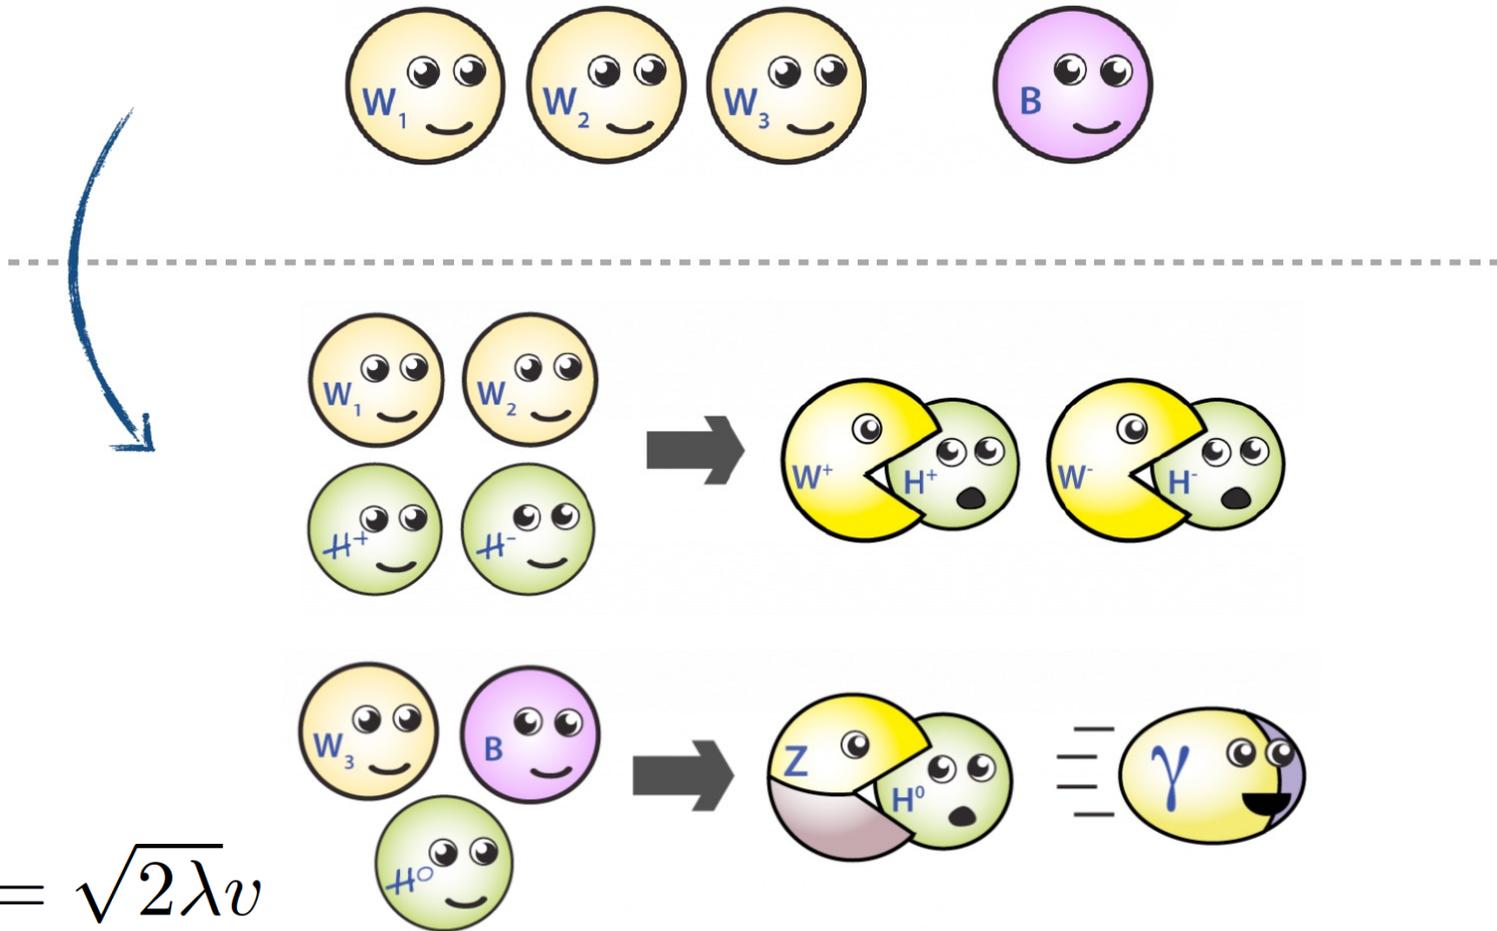

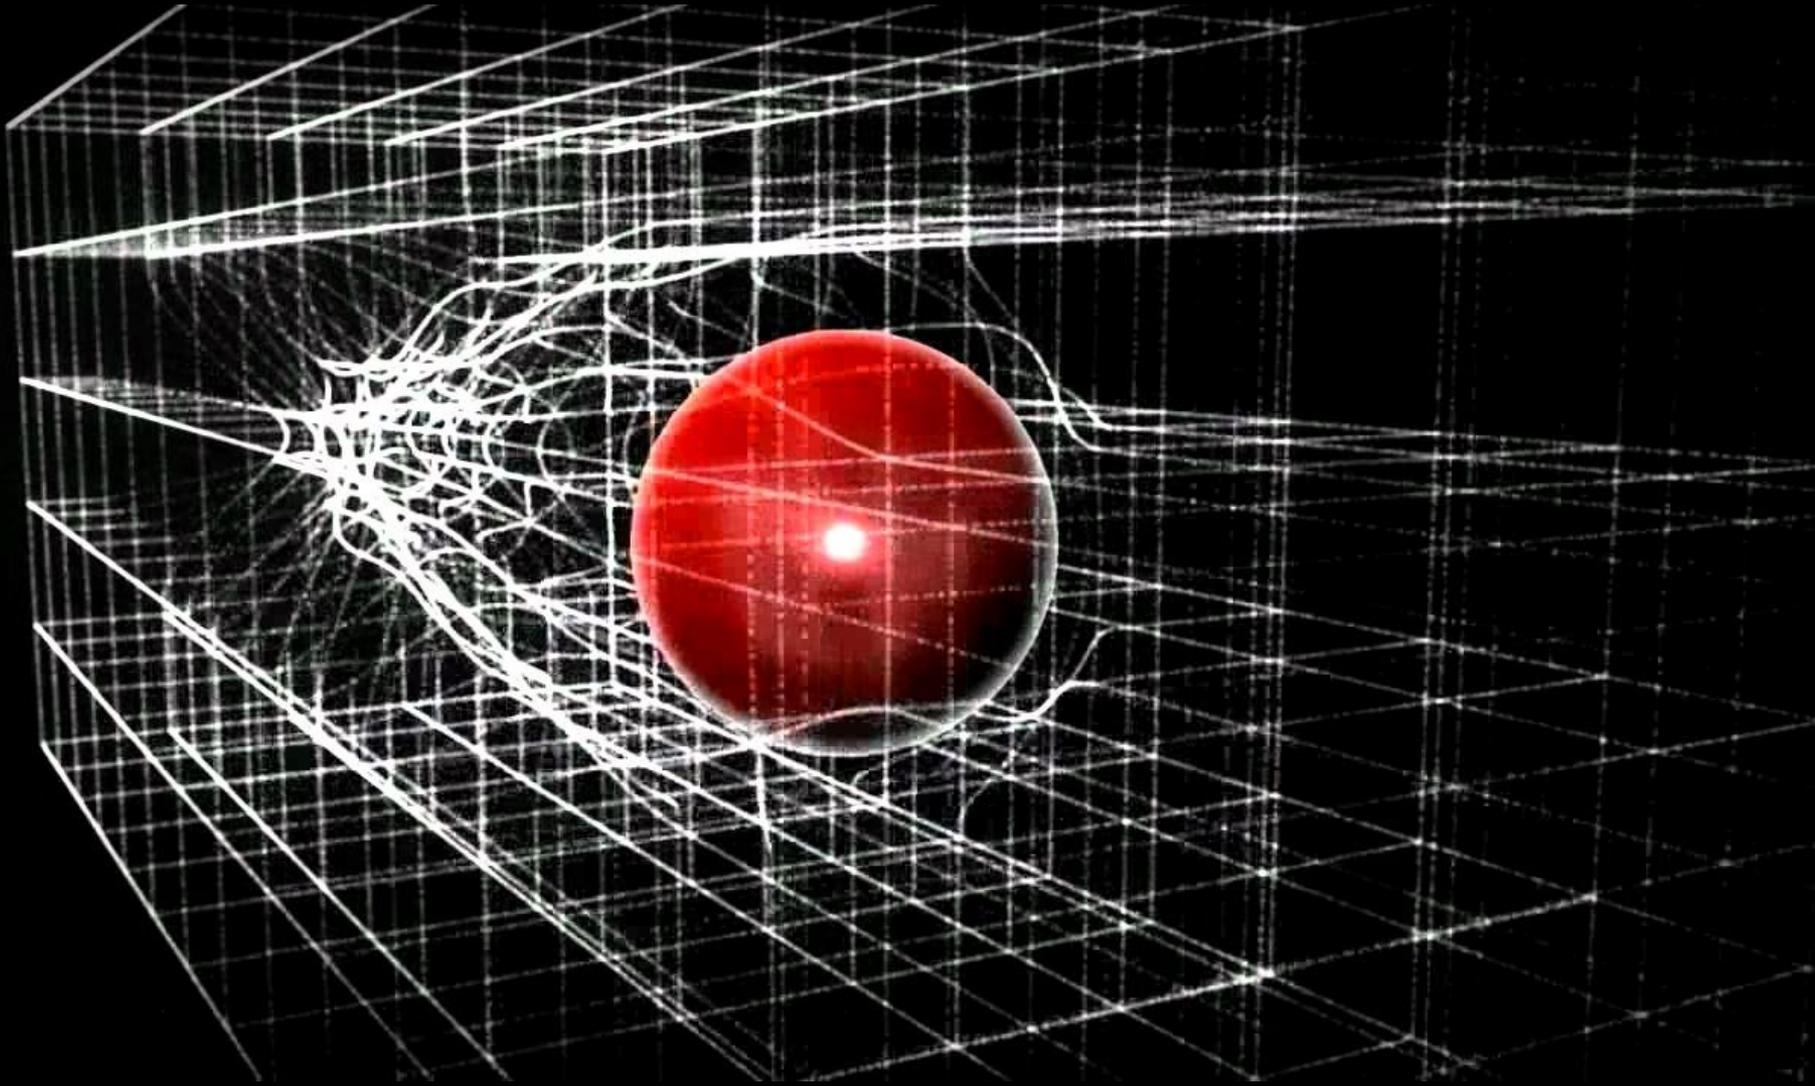

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

# EWK Symmetry Breaking in Pictures

$$m_h = \sqrt{2\lambda}v$$

# Higgs Properties

- Mass  $m_h = \sqrt{2\lambda}v$
- Spin: 1 degree of freedom  $\Rightarrow 0$
- Couplings:
- To gauge bosons

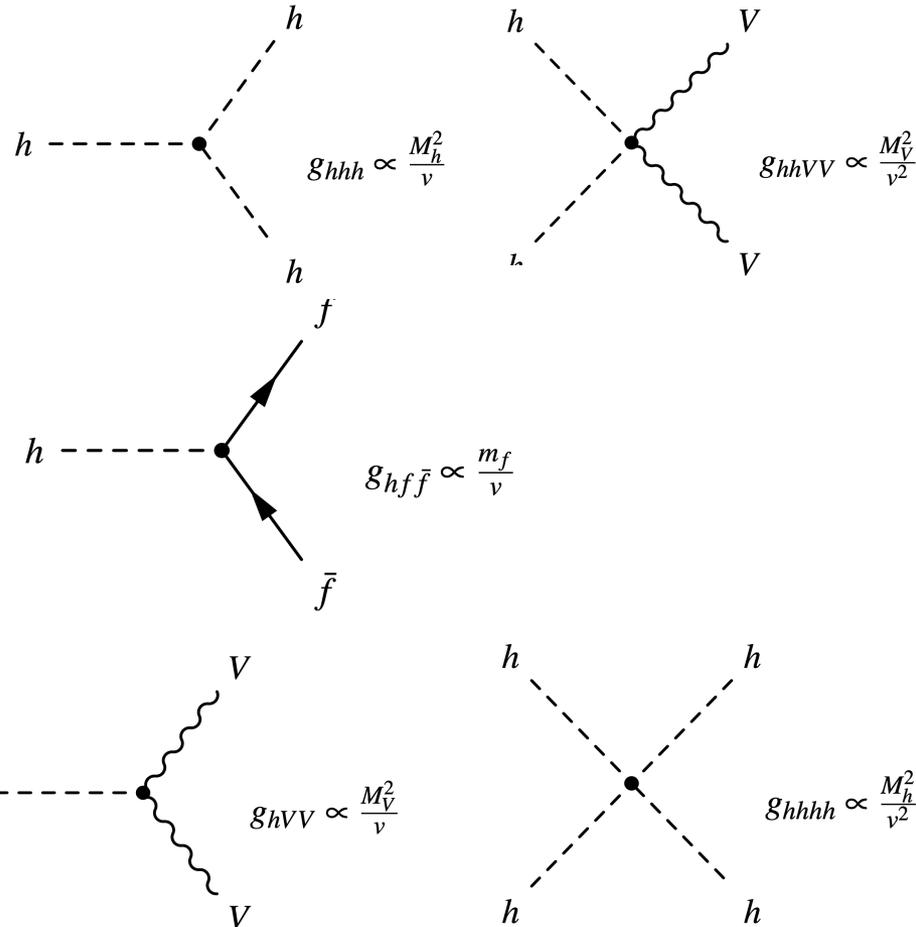

$$g_{hVV} \propto \frac{M_V^2}{v} \quad g_{hhVV} \propto \frac{M_V^2}{v^2}$$

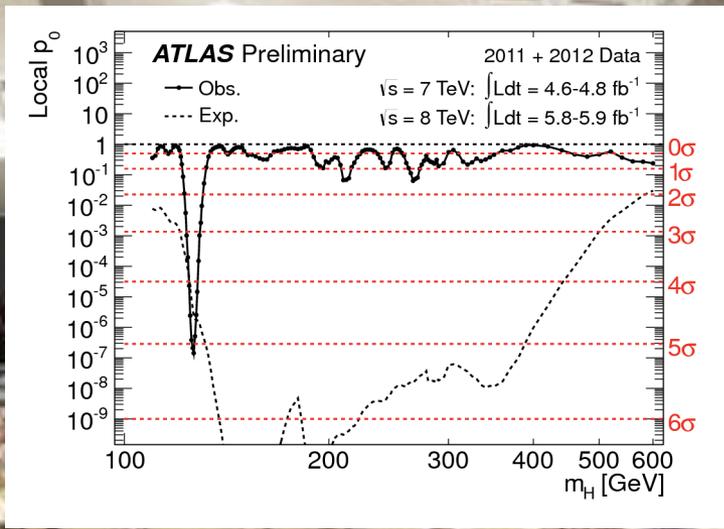

- Yukawa couplings to fermions

$$g_{hf\bar{f}} \propto \frac{m_f}{v}$$

- Self-couplings

$$g_{hhh} \propto \frac{M_h^2}{v} \quad g_{hhhh} \propto \frac{M_h^2}{v^2}$$

# The Long Way to Discovery

# A PHENOMENOLOGICAL PROFILE OF THE HIGGS BOSON

John ELLIS, Mary K. GAILLARD \* and D.V. NANOPOULOS \*\*  
*CERN, Geneva*

Received 7 November 1975

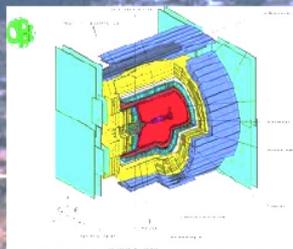

We should perhaps finish with an apology and a caution. We apologize to experimentalists for having no idea what is the mass of the Higgs boson, unlike the case with charm <sup>3),4)</sup> and for not being sure of its couplings to other particles, except that they are probably all very small. For these reasons we do not want to encourage big experimental searches for the Higgs boson, but we do feel that people performing experiments vulnerable to the Higgs boson should know how it may turn up.

FIT

Backgrounds +

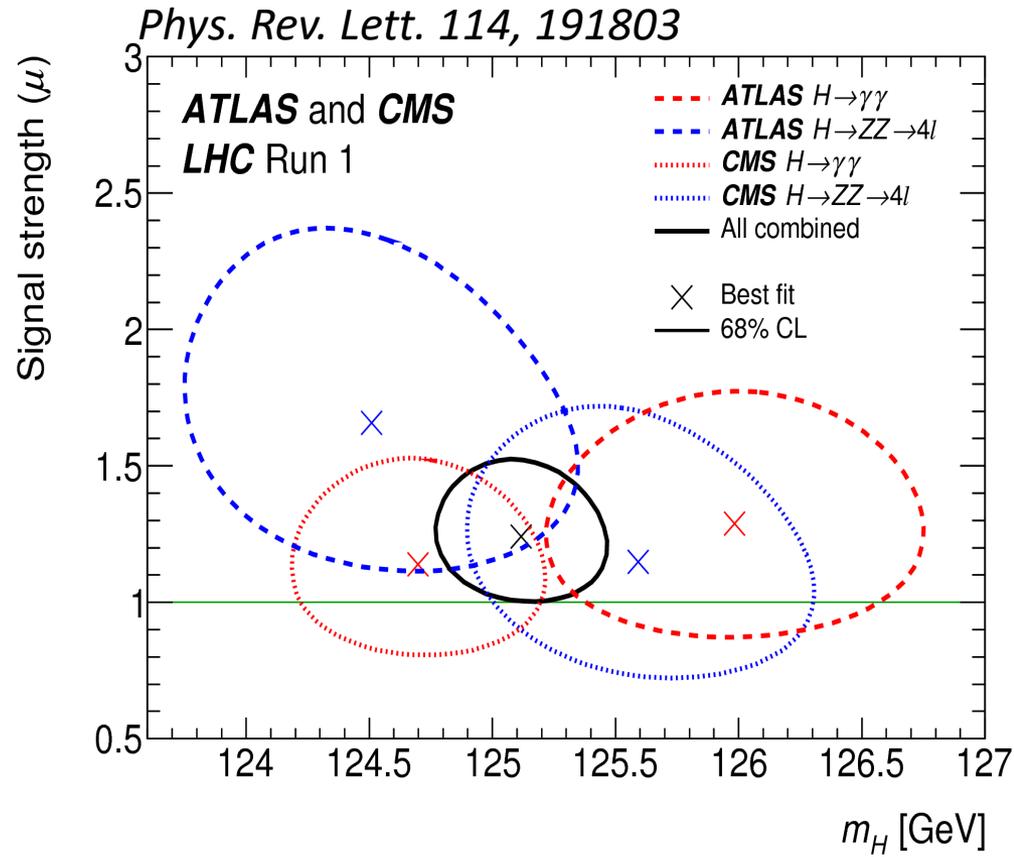

# Signal strength measurements

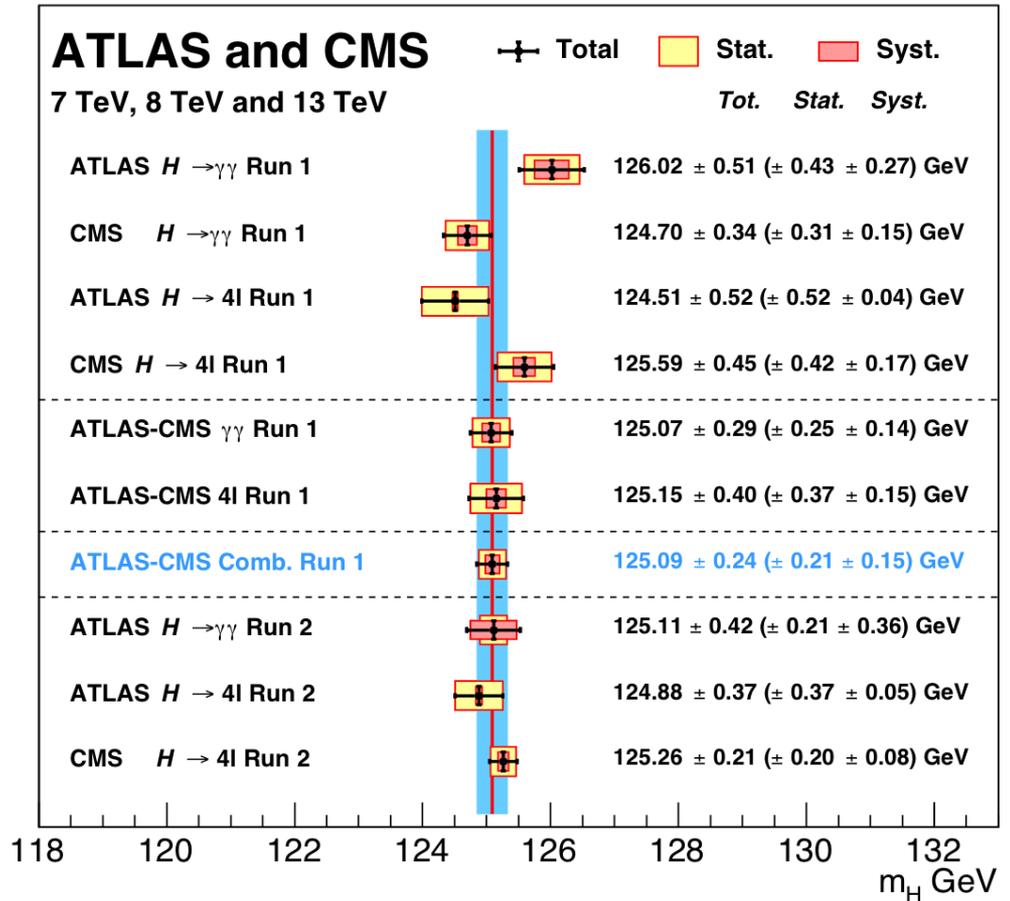

# Higgs boson mass

- Mass: around 125GeV  
**Was the only unknown SM parameter** 😊
- For a while, different mass values were being measured in ATLAS and CMS, and in different channels
- Numbers evolved with accumulated statistics

# Higgs boson mass

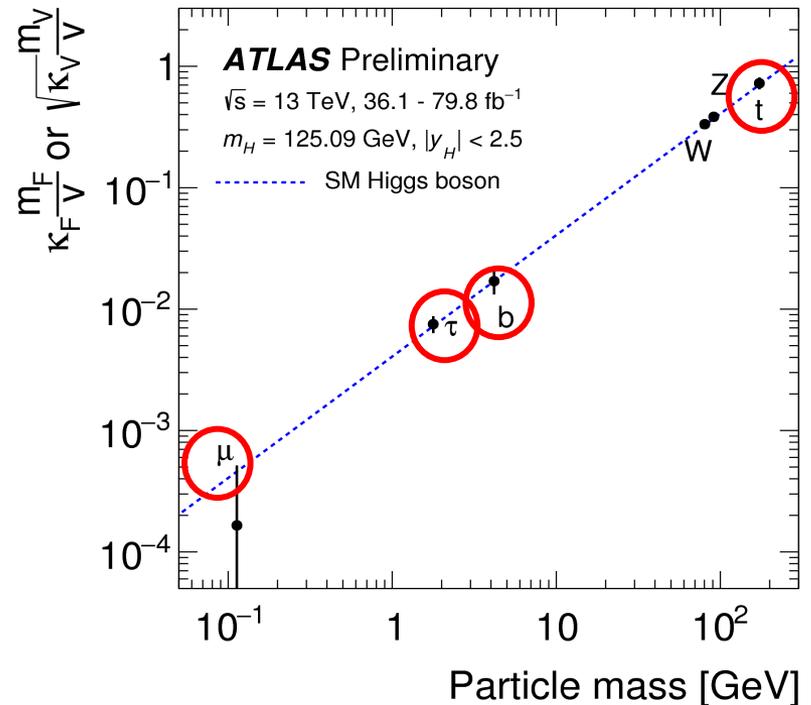

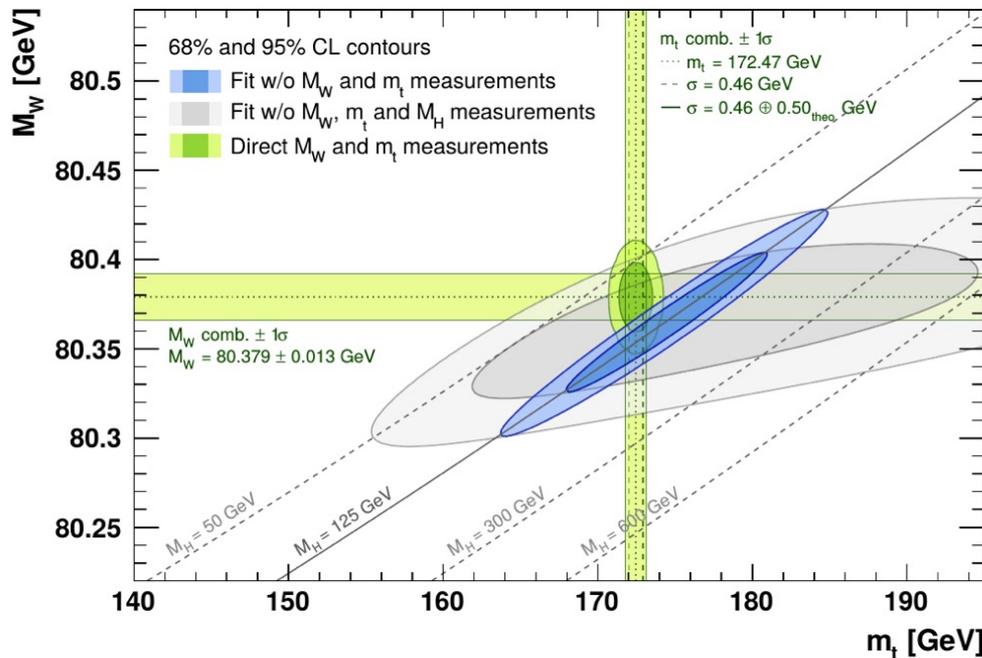

- Mass measurement from
  - $H \rightarrow ZZ^* \rightarrow 4l$
  - $H \rightarrow \gamma\gamma$
- Precision at the permille level achieved

# Exploring the electroweak scale

- Precision measurements of  $m_W$ ,  $m_t$ ,  $m_H$  are stringent tests of the SM at the EW scale
  - E.g. excluding measured  $m_H$ , global EW fit gives  $m_H = 90 \pm 21$  GeV (1.7  $\sigma$  tension) driven in part by  $m_{\text{top}}$

arXiv:1803.01853

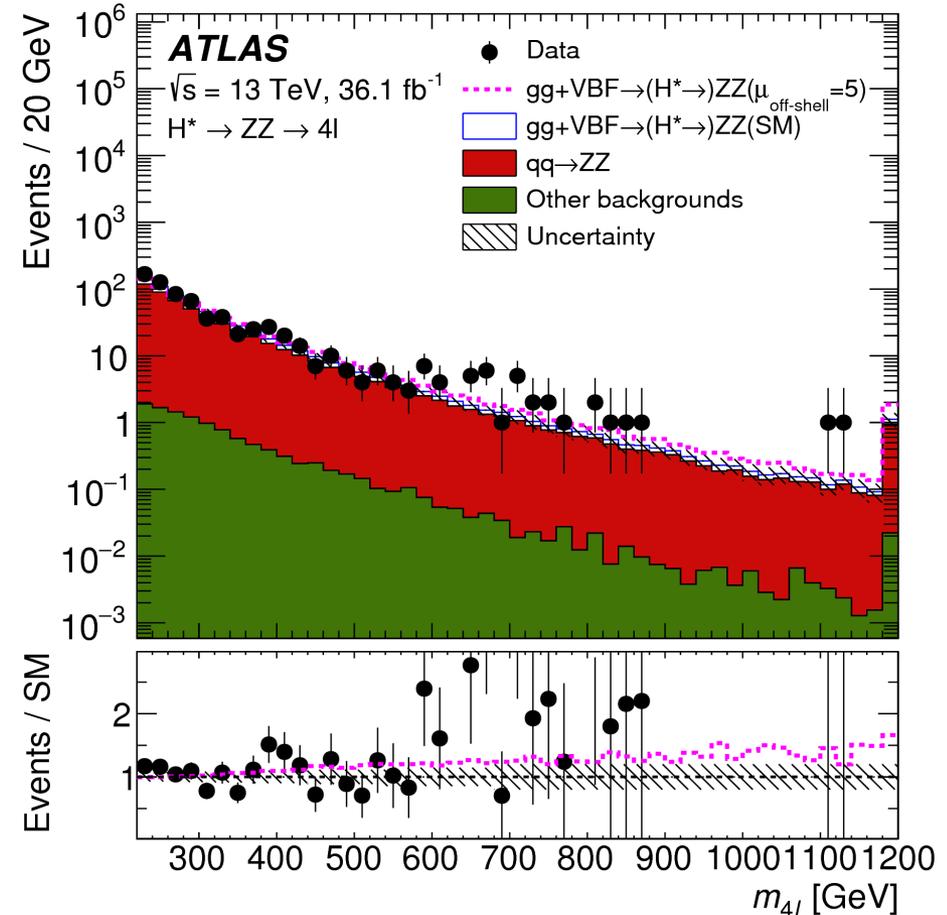

# Higgs boson width

- SM Higgs width  $\Gamma_H \sim 4.1$  MeV
  - Too small to be measured directly
  - Best direct limit from CMS:
    - $\Gamma_H < 1.1$  GeV @ 95% CL
- Off-shell Higgs production sensitive(\*) to  $\Gamma_H$

$$\frac{\mu_{\text{off-shell}}}{\mu_{\text{on-shell}}} = \frac{\kappa_{g,\text{off-shell}}^2 \cdot \kappa_{Z,\text{off-shell}}^2}{\kappa_{g,\text{on-shell}}^2 \cdot \kappa_{Z,\text{on-shell}}^2} \frac{\Gamma_H}{\Gamma_H^{SM}}$$

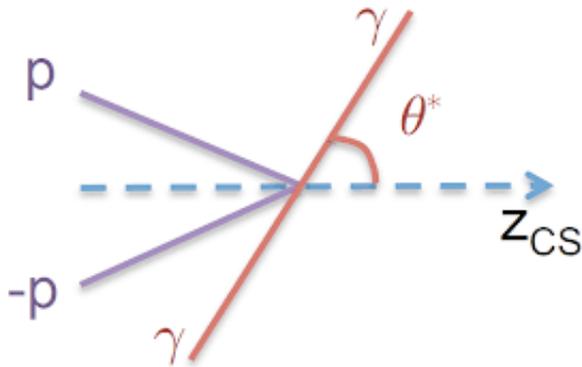

- ATLAS measurement:
  - $pp \rightarrow H \rightarrow ZZ \rightarrow 4l$  and  $ZZ \rightarrow 2l2\nu$
  - $m(H) > 2 m(Z)$
  - 36.1 fb<sup>-1</sup> of 13 TeV data
  - Observed (expected) limit:
    - $\Gamma_H < 14.4$  (15.2) MeV

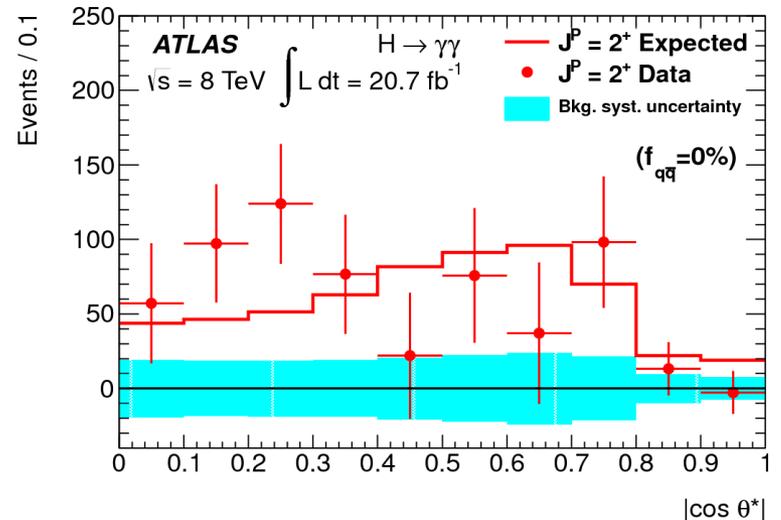

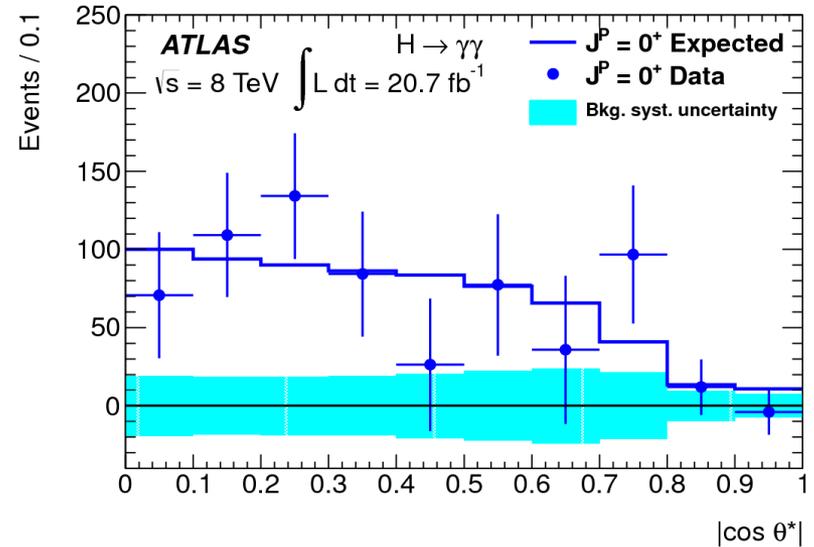

(\*) Assume interference term with  $gg \rightarrow ZZ$  proportional to  $K_{g,\text{off-shell}} \cdot K_{Z,\text{off-shell}}$

# Measuring the Higgs Spin

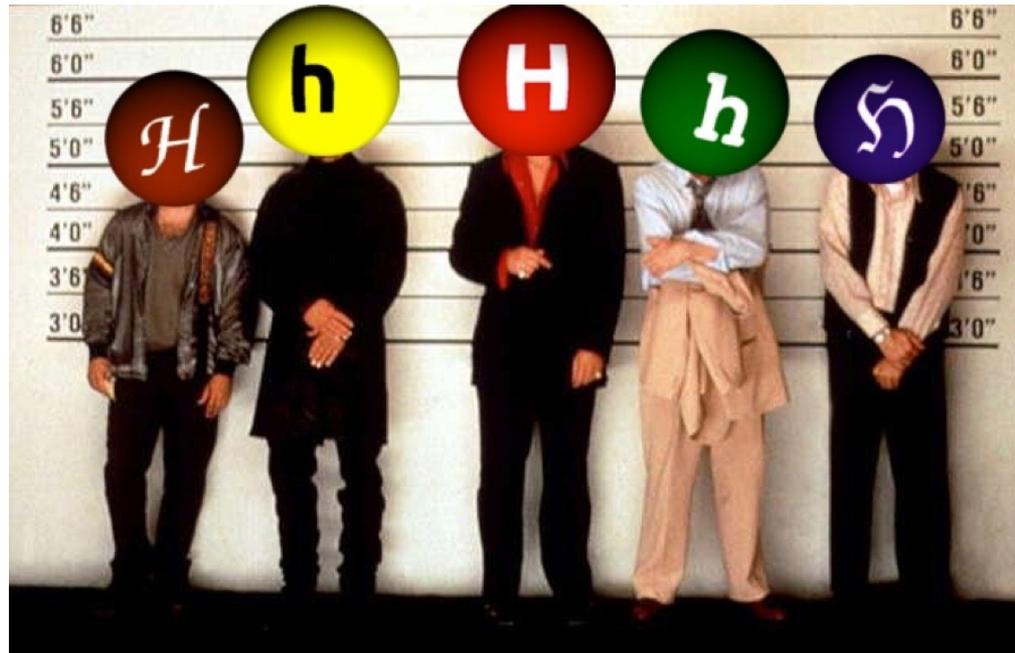

- Polar angle  $\theta$  in the rest frame of the diphoton system (Collins-Soper frame)

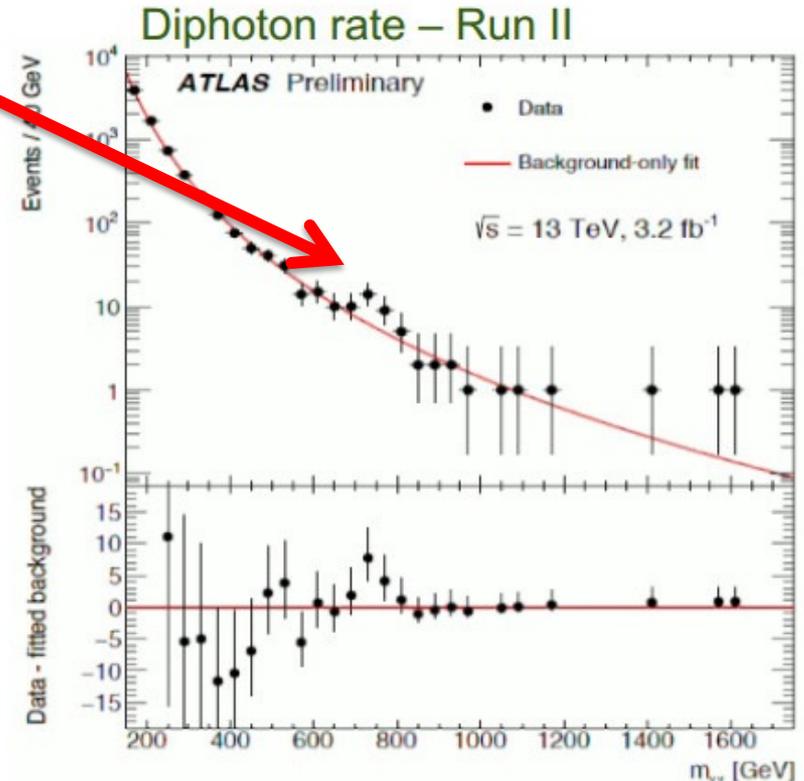

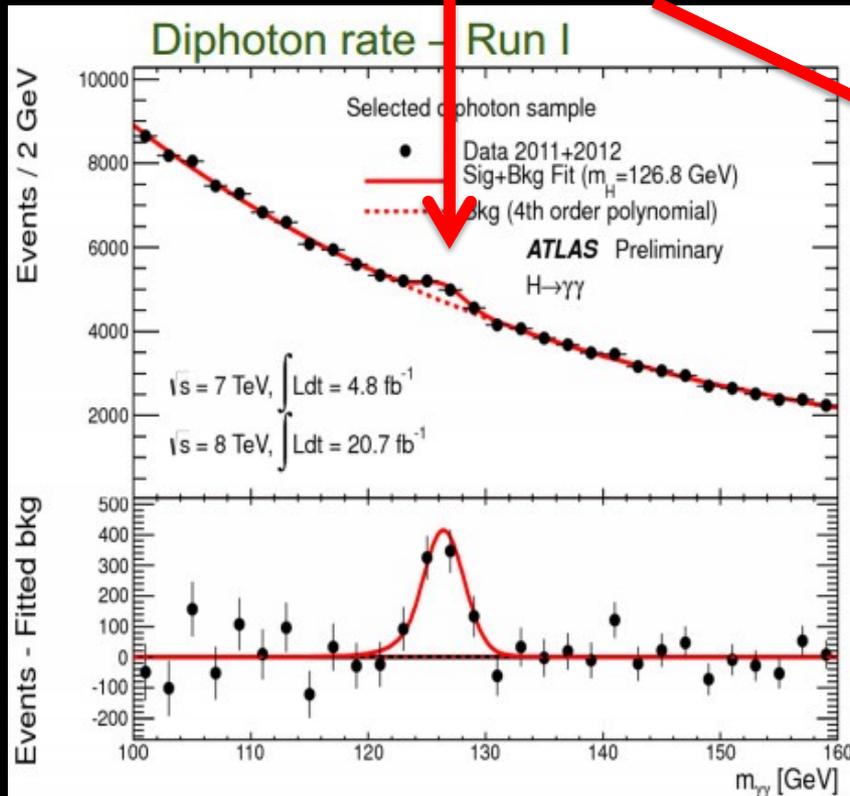

$$|\cos \Theta^*| = \frac{|\sinh(\Delta\eta^{\gamma\gamma})|}{\sqrt{1 + \frac{p_{T,\gamma\gamma}^2}{m_{\gamma\gamma}^2}}} \frac{2p_T^{\gamma_1} p_T^{\gamma_2}}{m_{\gamma\gamma}^2}$$

# Casting a wider net

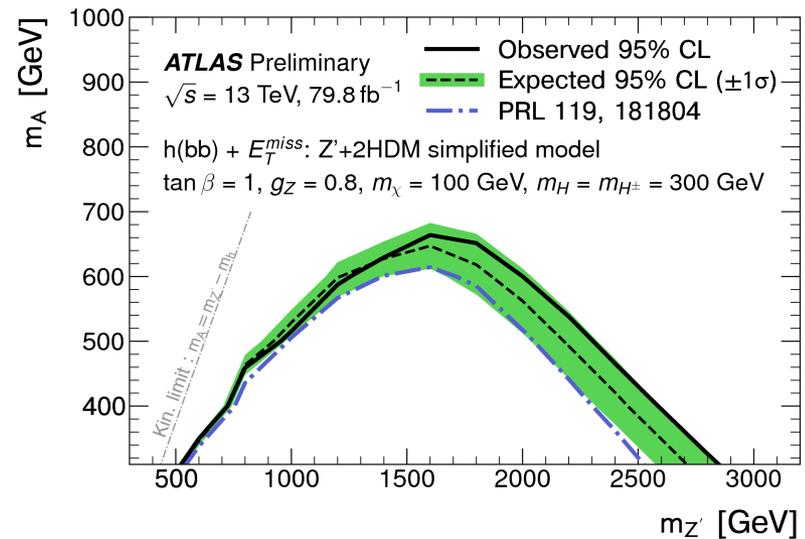

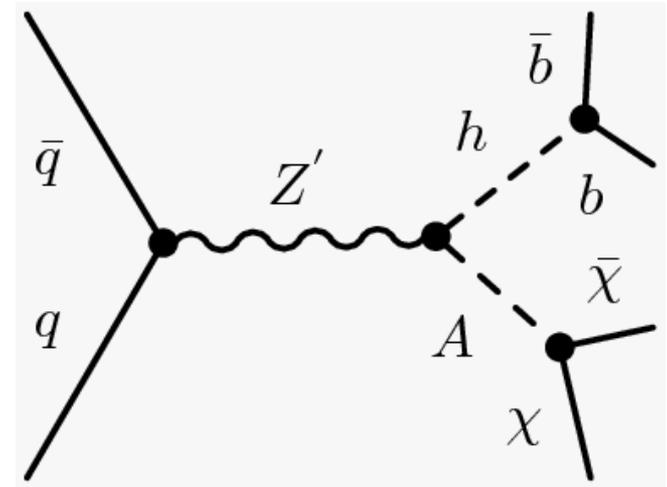

# Additional Higgs bosons?

# Higgs + Dark Matter

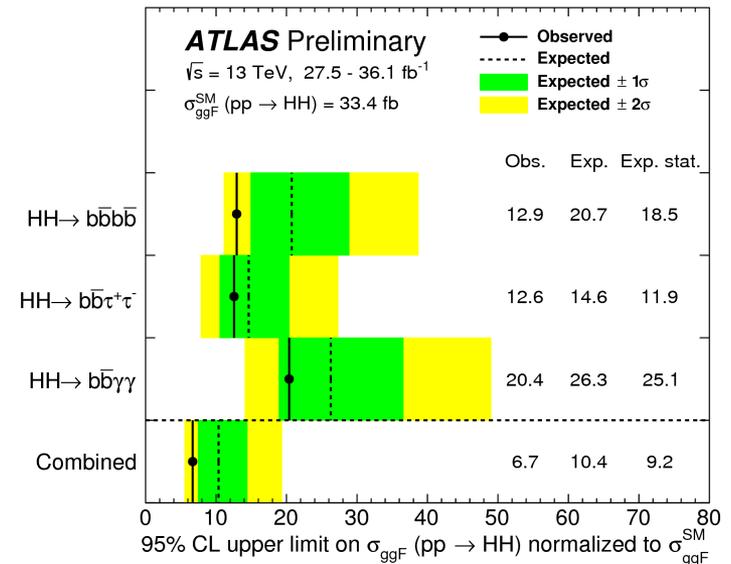

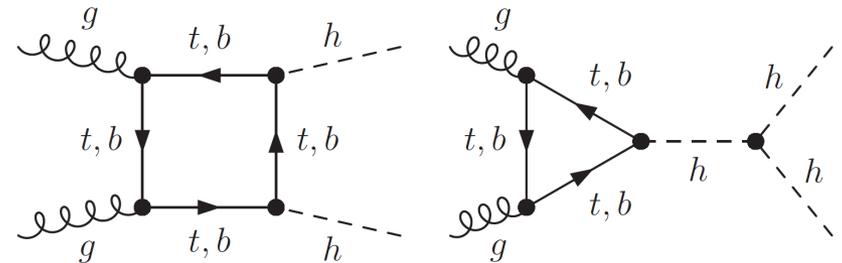

- Used  $79.8 \text{ fb}^{-1}$  of 13 TeV data
  - High  $E_T^{\text{miss}}$  ( $>150 \text{ GeV}$ ) and b-tagging to suppress backgrounds
  - Reconstruct b-jets as 2 small jets or merged variable-radius (VR) track jets
- Signal benchmark: Type-II 2HDM +  $U(1)_{Z'}$  symmetry (Z'-2HDM)
- Main backgrounds:  $t\bar{t}$ , W/Z+jets
- Excluded region in  $m_A - m_{Z'}$  plane

# Triple Higgs coupling

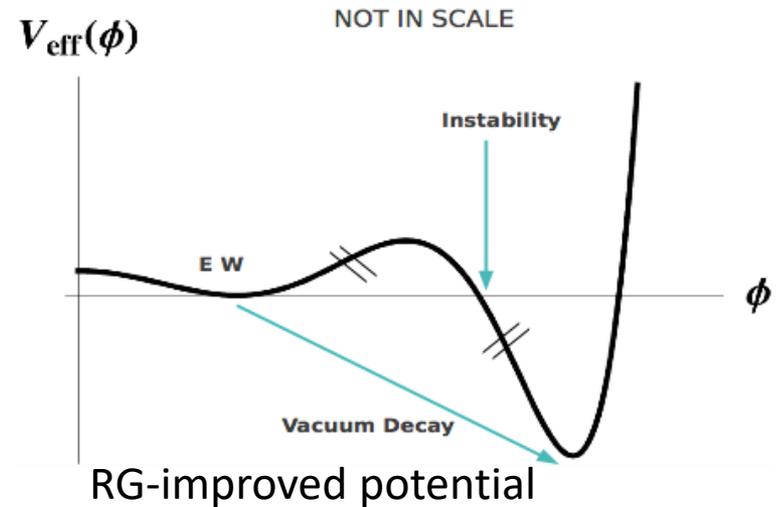

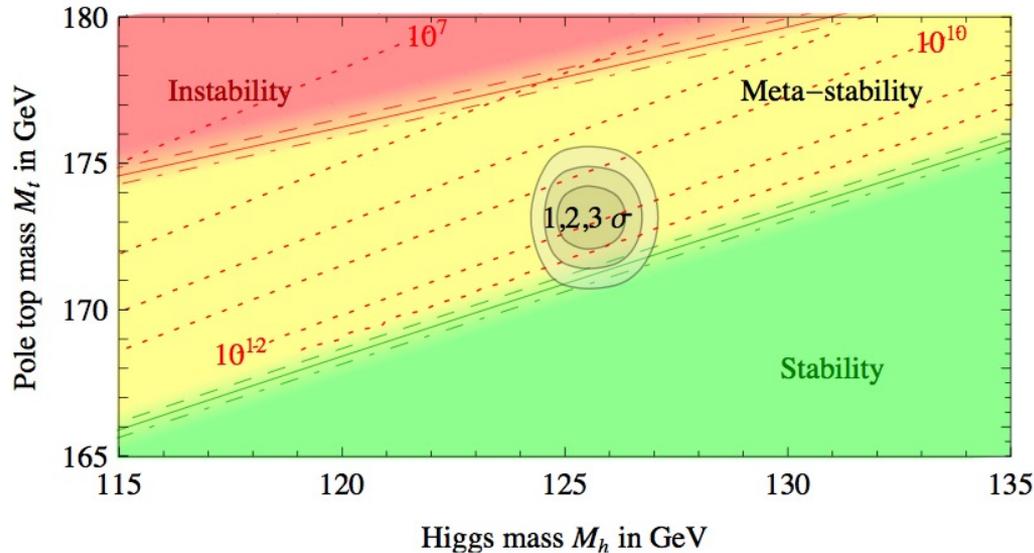

- The triple Higgs coupling  $\lambda_{HHH}$  can be probed through di-Higgs production
- Very suppressed in SM!
  - Negative interference between LO diagrams
  - Cross section 1500x less than ggF
- Wide range of decay BR and channel purity
- $bb\tau\tau$  analysis:
  - Used  $36 \text{ fb}^{-1}$  of 13 TeV data
  - Final state BR( $bb\tau\tau$ )=7%
  - Non-Resonant 95% CL limit:  
 $\mu < 12.7$  observed (**14.8 expected**)
- **Combination: at  $\approx 10$  x SM sensitivity**  
– with 3% of the HL-LHC luminosity analyzed

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

Di-Higgs combination plot [here](#)

# A bit of fun...

- What if...
  - At higher orders, Higgs potential doesn't have to be stable
  - Depending on  $m_t$  and  $m_H$  second minimum can be lower than EW minimum  $\Rightarrow$  tunneling between EW vacuum and true vacuum?!
- “For a narrow band of values of the top quark and Higgs boson masses, the Standard Model Higgs potential develops a shallow local minimum at energies of about  $10^{16}$  GeV, where primordial inflation could have started in a cold metastable state”, I. Masina, arXiv:1403.5244 [astro-ph.CO]

ATLAS-CONF-2020-058

29th October 2020

## Measurement of the Higgs boson decaying to $b$ -quarks produced in association with a top-quark pair in $pp$ collisions at $\sqrt{s} = 13 \text{ TeV}$ with the ATLAS detector

The ATLAS Collaboration

The associated production of a Higgs boson with a top-quark pair is measured in events characterised by the presence of one or two electrons or muons. The Higgs boson decay into a  $b$ -quark pair is considered. The analysed data, corresponding to an integrated luminosity of  $139 \text{ fb}^{-1}$ , were collected in proton-proton collisions at the Large Hadron Collider between 2015 and 2018 at a centre-of-mass energy of  $\sqrt{s} = 13 \text{ TeV}$ . The measured signal strength, defined as the ratio of the measured signal yield to that predicted by the Standard Model, is  $0.43^{+0.36}_{-0.33}$ . This result corresponds to an observed (expected) significance of 1.3 (3.0) standard deviations, in agreement with the Standard Model prediction. For the first time, the signal strength is measured differentially in bins of the Higgs boson transverse momentum in the simplified template cross-section framework, including a boosted selection targeting Higgs boson transverse momentum above 300 GeV.

# ttH CP measurement

Recent measurement in this channel gives limits to a CP-odd admixture in the Higgs Yukawa coupling

PRL 125 061802

# CP violation results in the ATLAS experiment

R. Gonalo (U.Coimbra / LIP) on behalf of the ATLAS Collaboration  
Higgs Hunting, Orsay-Paris, Sep.12-14 2022

# CP Violation in the Higgs Sector?

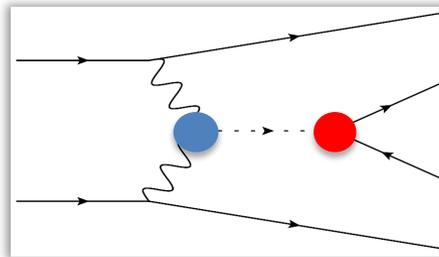

- Sakharov conditions for a matter-dominated universe require CP violation<sup>(1)</sup>
- Some CP-violating processes are well known and measured:
  - Described with complex phases in CKM-matrix - quark mixing
  - Maybe in PNMS-matrix as well - neutrino mixing
- But insufficient, by orders of magnitude, to explain baryon asymmetry<sup>(1)</sup>
- CP violation in Higgs-sector?
  - Possible in some models with extended Higgs sector (e.g. some 2HDMs)
  - **Mixing** of scalar (CP-even) and pseudo-scalar (CP-odd) Higgs states would make CP violation an enticing possibility
- What do we know about Higgs CP properties?
  - In the SM, Higgs scalar is a CP eigenstate with  $J^{CP} = 0^{++}$
  - Pure  $J^P = 0^-$  hypothesis for observed Higgs boson was ruled out in Run 1<sup>(2)</sup>
  - But hypothesis of a CP-odd admixture is far from being constrained experimentally!

<sup>(1)</sup> See e.g. Mod.Phys.Lett.A 9 (1994) 795-810

<sup>(2)</sup> See e.g. Eur.Phys.J C75 (2015) 476

# How to search for a CP-odd admixture?

- Effect of CP-odd components on **bosonic couplings** parametrized as expansion with higher order terms suppressed by powers of scale of new physics  $\Lambda$
- Could explain why a CP-odd admixture has not been seen

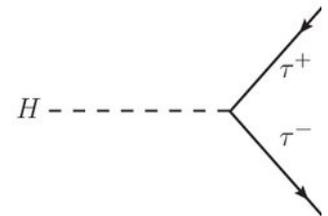

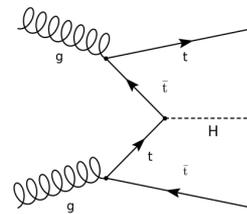

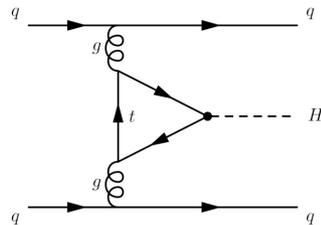

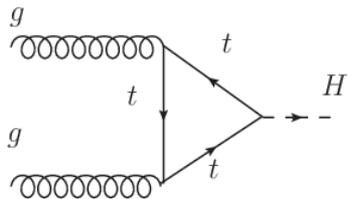

- **Fermionic couplings** are affected at tree level
- Mixing angle  $\alpha$  between CP-even and CP-odd coupling components
- More notable for heavier fermions due to enhanced coupling

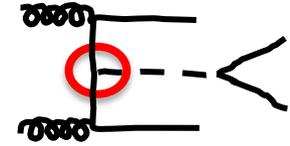

$$\mathcal{L}_{VVH} = \mathcal{L}_{VVH,SM} + \frac{1}{\Lambda^2} c \phi \tilde{V}_{\mu\nu} V^{\mu\nu} + \dots$$

$$\mathcal{L}_{ffH} = \kappa'_f y_f \phi \bar{\psi}_f (\cos \alpha + i \gamma_5 \sin \alpha) \psi_f$$

**YpXn** Y charged pions; X neutral pions

$$\mathcal{L}_{H\tau\tau} = -\frac{m_\tau}{v} \kappa_\tau (\cos \phi_\tau \bar{\tau}\tau + \sin \phi_\tau \bar{\tau}i\gamma_5\tau)H$$

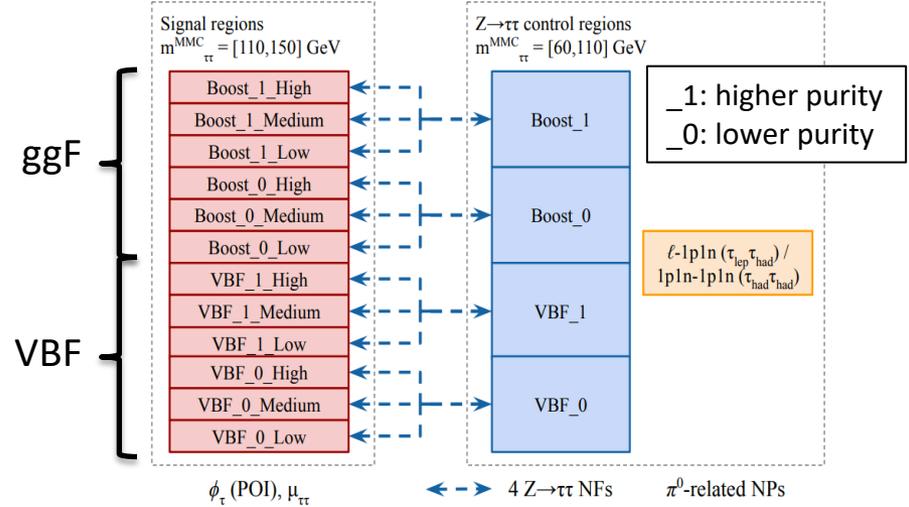

- Angle between  $\tau$  decay planes in H rest frame sensitive to CP mixing angle  $\phi_\tau$
- Due to neutrinos, use  $\phi^{*CP}$  as proxy:
  - Acoplanarity angle between  $\tau$  decay planes in **Zero Momentum Frame** of **visible** decay products
- $\phi^{*CP}$  reconstructed with dedicated methods for semi-exclusive decay modes
  - Total branching ratio in targeted decay modes: 68%

# H- $\tau$ Coupling in inclusive production

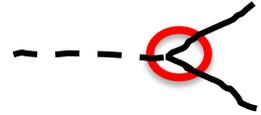

Decay channel	Decay mode combination	Method	Fraction in all $\tau$ lepton pair decays
$\tau_{lep} \tau_{had}$	$\ell$ -1p0n	IP	8.1%
	$\ell$ -1p1n	IP- $\rho$	18.3%
	$\ell$ -1pXn	IP- $\rho$	7.6%
	$\ell$ -3p0n	IP- $a_1$	6.9%
$\tau_{had} \tau_{had}$	1p0n-1p0n	IP	1.3%
	1p0n-1p1n	IP- $\rho$	6.0%
	1p1n-1p1n	$\rho$	6.7%
	1p0n-1pXn	IP- $\rho$	2.5%
	1p1n-1pXn	$\rho$	5.6%
	1p1n-3p0n	$\rho$ - $a_1$	5.1%

$YpXn$  Y charged pions; X neutral pions

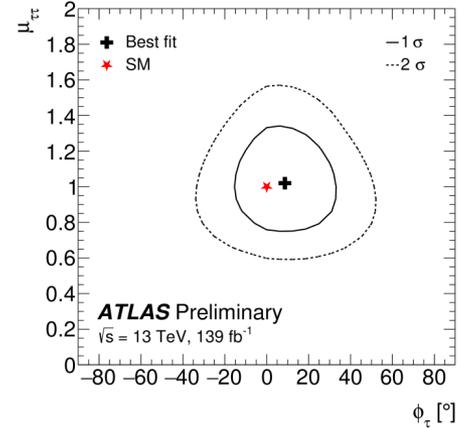

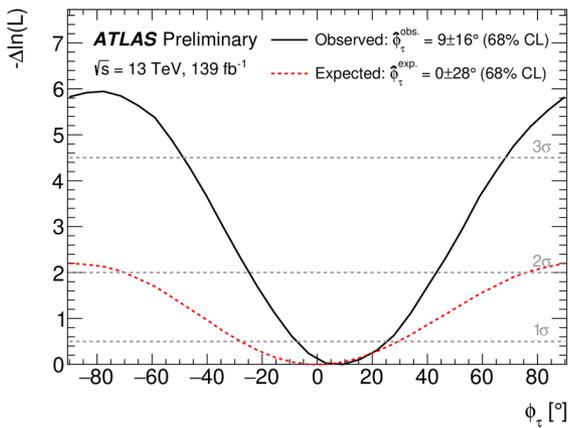

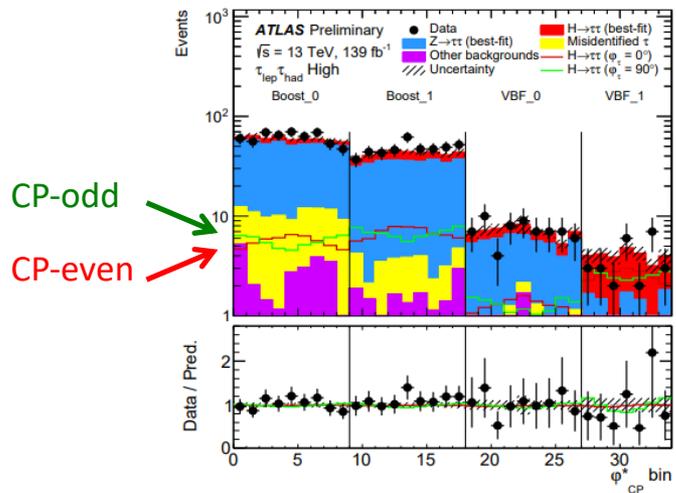

- 24 Signal categories and 10 Control Regions
  - **2 channels**  $\times$  **VBF or Boost** ( $ggF p_{\tau^H} > 100$  GeV)  $\times$  **2 purity regions**  $\times$  High/Medium/Low **sensitivity**
- Angle reconstruction requires excellent performance:
  - Particle flow based  $\tau_{had}$  reconstruction
  - $\pi^0 \rightarrow \gamma\gamma$  and vertex / impact parameter reconstruction
  - Both efficiency and purity around 80% for dominant decays

# H-τ Coupling in inclusive production

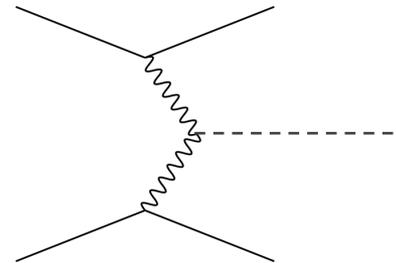

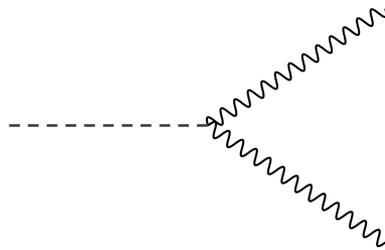

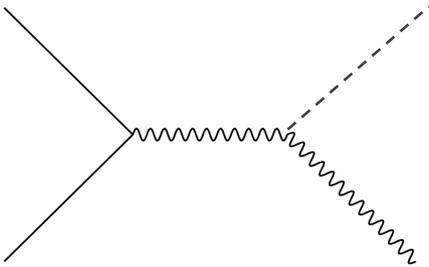

- Simultaneous fit in all regions
- Analysis leaves  $\mu$  free to float – agnostic with respect to rate effects
- Best fit observed:  $\phi_\tau = 9^\circ \pm 16^\circ$  (expected:  $\phi_\tau = 0^\circ \pm 28^\circ$ )
- Pure CP-odd ( $\alpha = 90^\circ$ ) disfavoured at  $3.4 \sigma$
- Dominant background is  $Z \rightarrow \tau\tau$ : constrained from Control Regions
- Statistics-dominated analysis; dominant systematic uncertainty from jet calibration

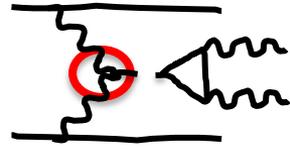

$$\mathcal{L}_{H\tau\tau} = -\frac{m_\tau}{v} \kappa_\tau (\cos \phi_\tau \bar{\tau}\tau + \sin \phi_\tau \bar{\tau}i\gamma_5\tau)H$$

# Bosonic Higgs Couplings

# HVV Coupling in Vector Boson Fusion

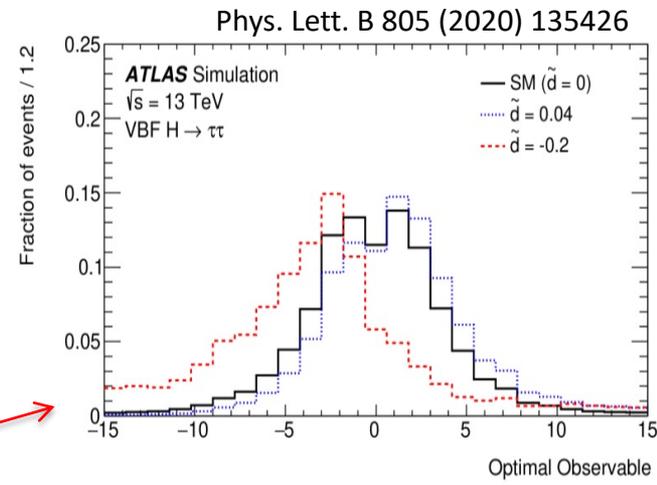

- New analysis: **VBF  $H \rightarrow \gamma\gamma$**
- Consider effective HVV Lagrangian augmented with dimension six **CP-odd** operators
- Strength of CP violation in VBF matrix element can be described by a single parameter<sup>(\*)</sup> giving:

$$\mathcal{M} = \mathcal{M}_{SM} + \tilde{d} \cdot \mathcal{M}_{CP-odd}$$

$$|\mathcal{M}|^2 = |\mathcal{M}_{SM}|^2 + \tilde{d} \cdot 2 \operatorname{Re}(\mathcal{M}_{SM}^* \mathcal{M}_{CP-odd}) + \tilde{d}^2 \cdot |\mathcal{M}_{CP-odd}|^2$$

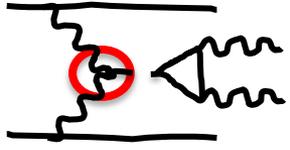

- Calculate LO matrix elements using 4-momenta of Higgs and VBF jets
  - Extract initial-state parton momentum fractions from jet momenta
- Use to calculate **Optimal Observable (OO)**:
  - Expected to be symmetric with mean value of zero if no CP-violation

$$OO = \frac{2 \operatorname{Re}(\mathcal{M}_{SM}^* \mathcal{M}_{CP-odd})}{|\mathcal{M}_{SM}|^2}$$

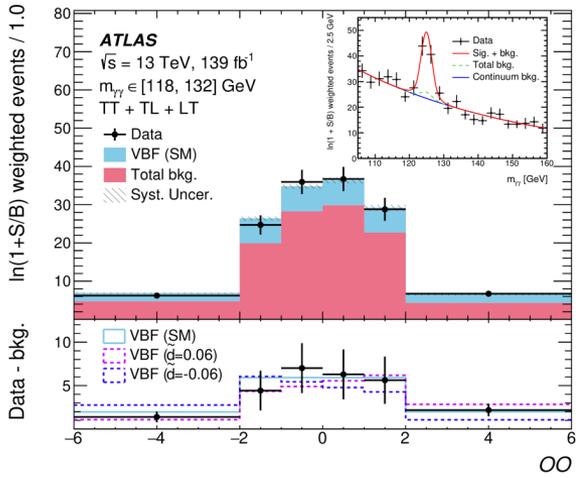

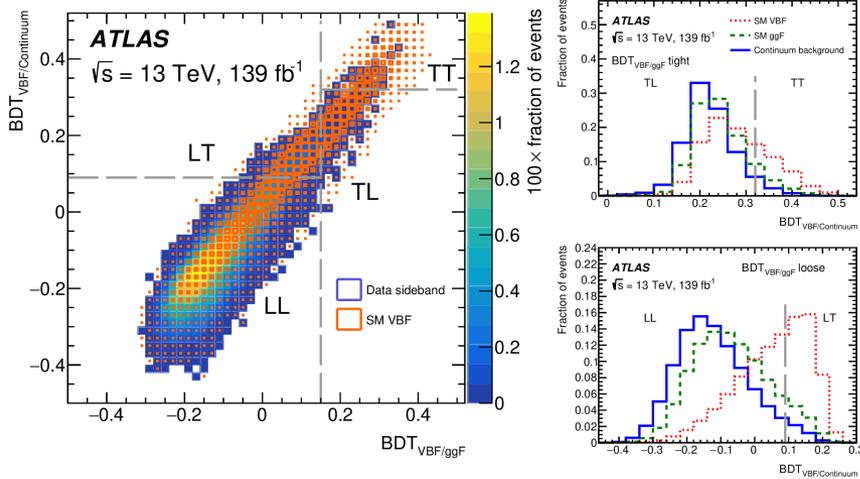

<sup>(\*)</sup> Slightly simplified scenario: see Phys. Lett. B 805 (2020) 135426, set:  $\tilde{d} = \tilde{d}_B$

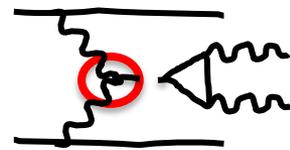

# HVV Coupling in Vector Boson Fusion

- Select events with  $\geq 2$  photons and  $\geq 2$  tag jets (energy flow)
- Increase signal purity with 2 BDTs:
  - **BDT<sub>VBF/ggF</sub>**: separate VBF signal from gluon-fusion Higgs production
  - **BDT<sub>VBF/Continuum</sub>**: separate VBF signal from continuum diphoton background
- Split into signal regions using BDT output: Tight-Tight (TT); Loose-Tight (LT); Tight-Loose (TL)
- In each OO bin extract signal yield from a fit to the di-photon mass spectrum
- Fit shape of Optimal Observable to extract the coefficient of the interference term  $\tilde{d}$ 
  - Pure **shape analysis** – signal normalisation is left floating in the fit to depend only on interference term

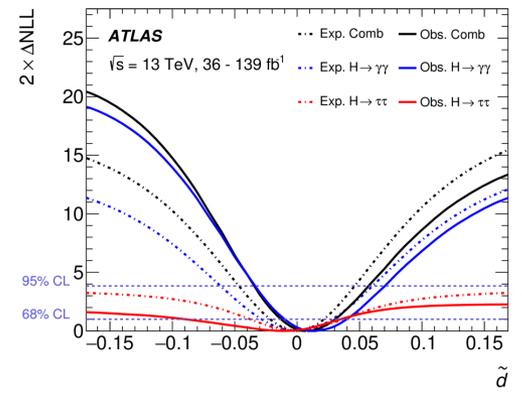

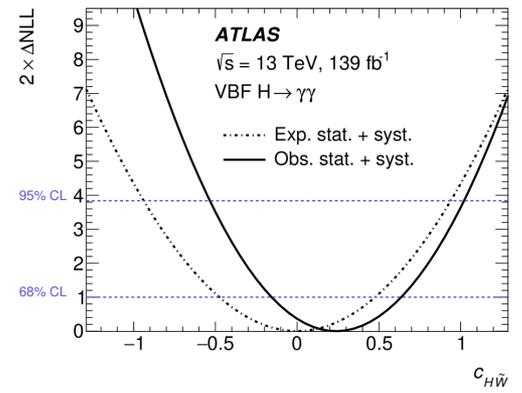

# HVV Coupling in Vector Boson Fusion

- Result interpretation with  $\tilde{d}$  (HISZ EFT operator basis) but also  $c_{H\tilde{W}}$  (Warsaw basis)
  - No improvement from using quadratic term – sensitivity driven by interference
- Results are the **strongest existing bounds** on CP violation in HVV
- Combination with previous analysis of VBF  $H \rightarrow \tau\tau$  ( $36 \text{ fb}^{-1}$ )
  - [Phys. Lett. B 805 \(2020\) 135426](#)
  - Confidence intervals further improved

# Summary & Outlook

- The search for a CP structure of Higgs boson couplings is being very actively pursued in ATLAS
  - Still much space for CP odd admixture, potential source for CP violation
  - Would be clear evidence for deeper theory, beyond the SM and might address fundamental question of baryon asymmetry
- Results generally in agreement with Standard Model CP-even hypothesis
- Several Run 2 measurements using  $139 \text{ fb}^{-1}$ 
  - Produced about 8 M Higgs bosons in Run 2!
  - A lot to expect from Run 3 and later!
- Today: showed only latest results in this presentation:
  - H-top Coupling in  $t\bar{t}H/tH$  production with  $H \rightarrow \gamma\gamma$ ,  $H \rightarrow b\bar{b}$
  - H- $\tau$  Coupling in VBF +  $hhF$  production
  - HVV Coupling in VBF,  $H \rightarrow \gamma\gamma$
  - More Run 2 analyses reaching results soon

Pure CP-odd  $t\bar{t}H$  coupling excluded  
at  $3.9 \sigma$   
Pure CP-odd  $H\tau\tau$  coupling excluded  
at  $3.4 \sigma$   
Strongest existing bounds on  
 $\tilde{d}$  and  $c_{H\tilde{W}}$

# Higgs Properties

- Mass  $m_h = \sqrt{2\lambda}v$
- Spin: 1 degree of freedom  $\Rightarrow 0$
- Couplings:
- To gauge bosons

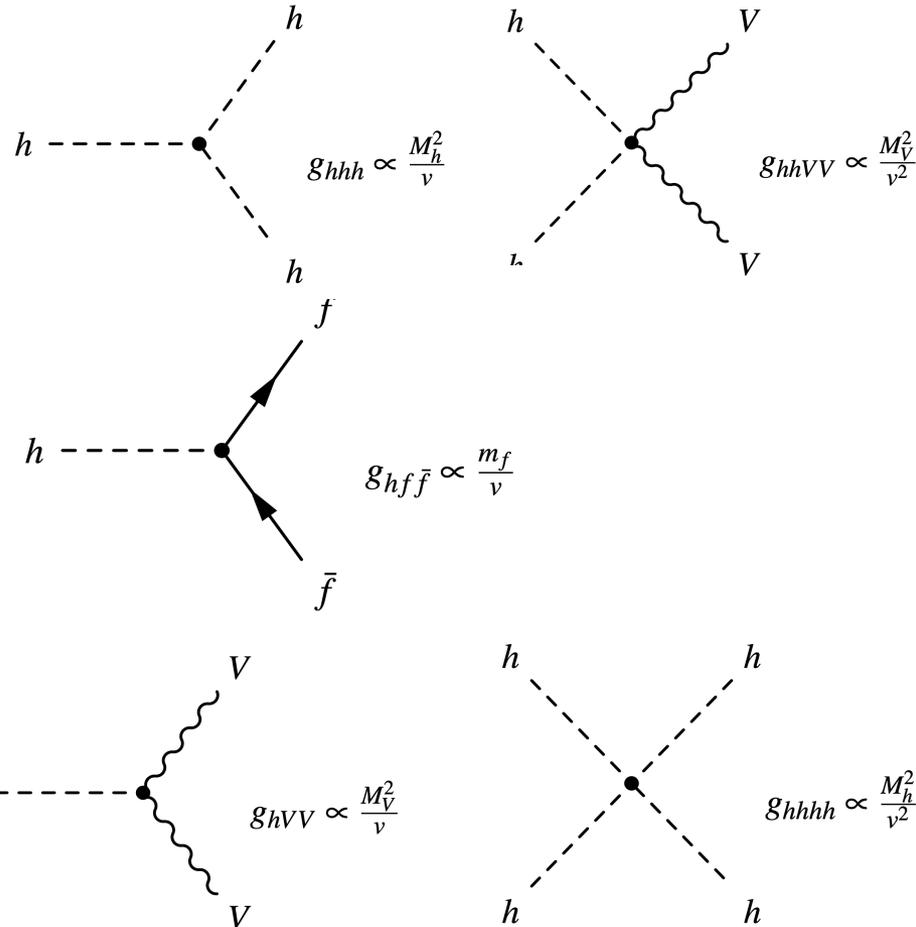

$$g_{hVV} \propto \frac{M_V^2}{v} \quad g_{hhVV} \propto \frac{M_V^2}{v^2}$$

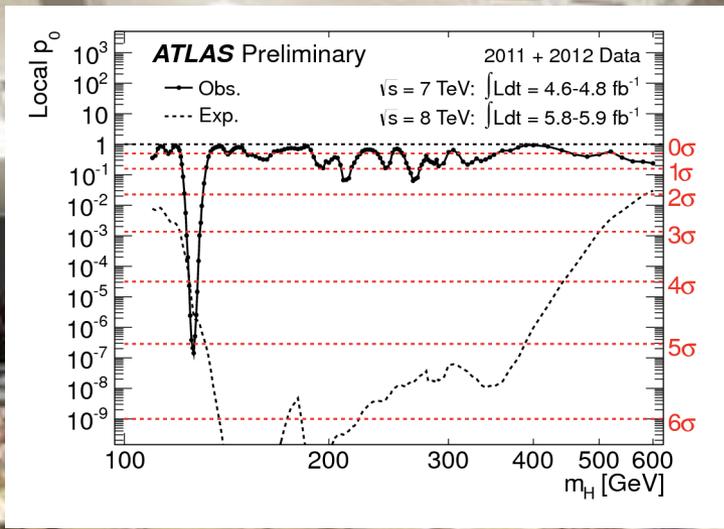

- Yukawa couplings to fermions

$$g_{hf\bar{f}} \propto \frac{m_f}{v}$$

- Self-couplings

$$g_{hhh} \propto \frac{M_h^2}{v} \quad g_{hhhh} \propto \frac{M_h^2}{v^2}$$

# The Long Way to Discovery

# A PHENOMENOLOGICAL PROFILE OF THE HIGGS BOSON

John ELLIS, Mary K. GAILLARD \* and D.V. NANOPOULOS \*\*  
*CERN, Geneva*

Received 7 November 1975

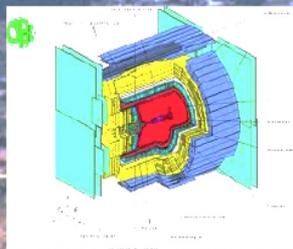

We should perhaps finish with an apology and a caution. We apologize to experimentalists for having no idea what is the mass of the Higgs boson, unlike the case with charm <sup>3),4)</sup> and for not being sure of its couplings to other particles, except that they are probably all very small. For these reasons we do not want to encourage big experimental searches for the Higgs boson, but we do feel that people performing experiments vulnerable to the Higgs boson should know how it may turn up.

Electron-positron collider up to  $s^{1/2} = 209$  GeV  
Integrated luminosity:  $\sim 700$  pb $^{-1}$

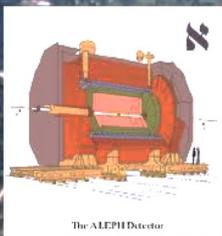

Shutdown: September 2000

# Searches at LEP

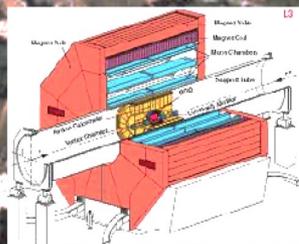

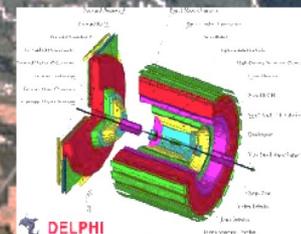

OPAL

ALEPH

DELPHI

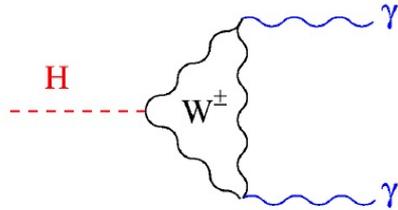

L3

# Low-mass searches at LEP

The decay branching ratios depend only on  $m_H$ :

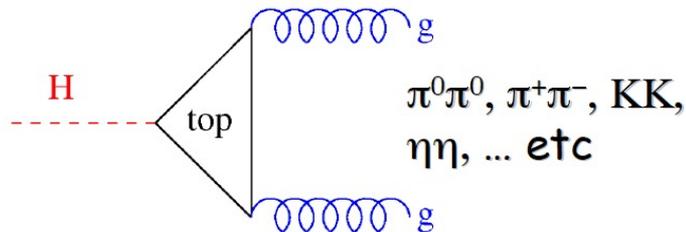

□  $m_H < 2m_e$ :  $H \rightarrow \gamma\gamma$  + large lifetime;

□  $m_H < 2m_\mu$ :  $H \rightarrow e^+e^-$  dominates;

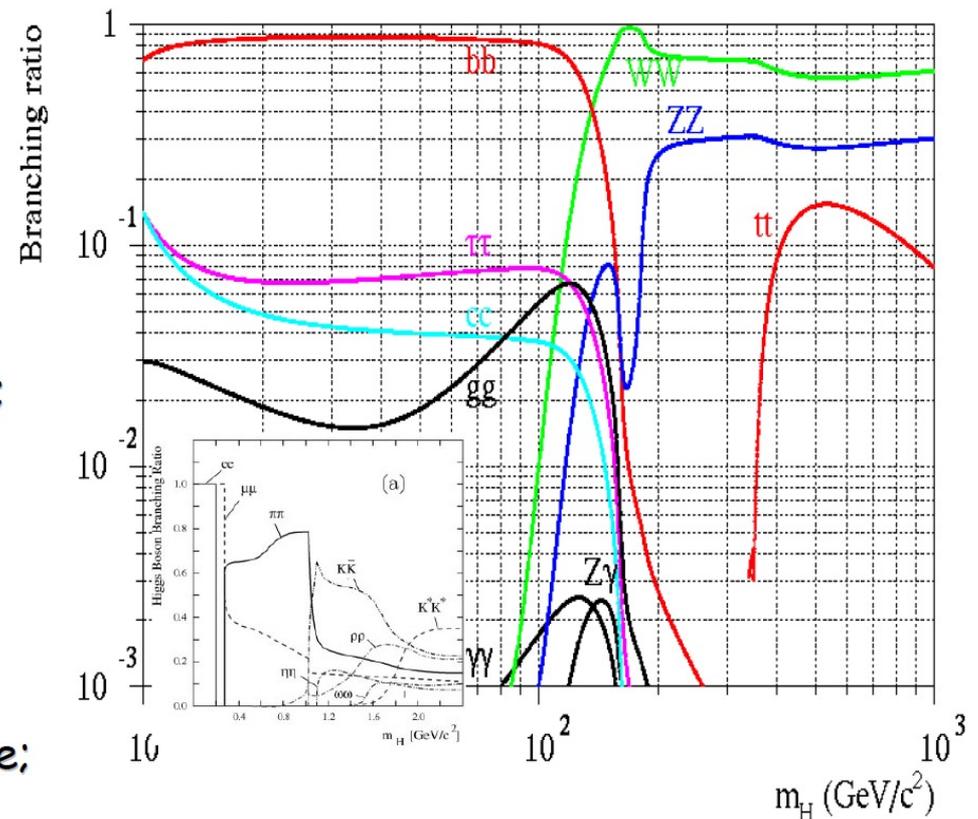

□  $m_H < 2m_\pi$ :  $H \rightarrow \mu^+\mu^-$  dominates;

□  $m_H < 3 - 4 \text{ GeV}$ :  $H \rightarrow gg$  dominates;

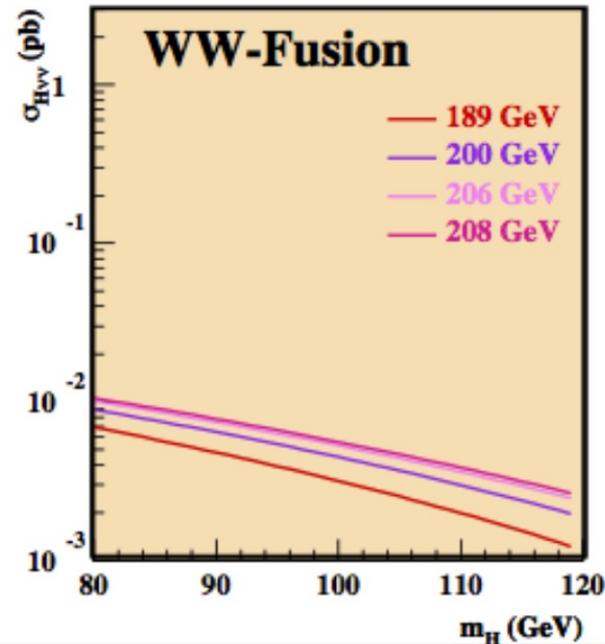

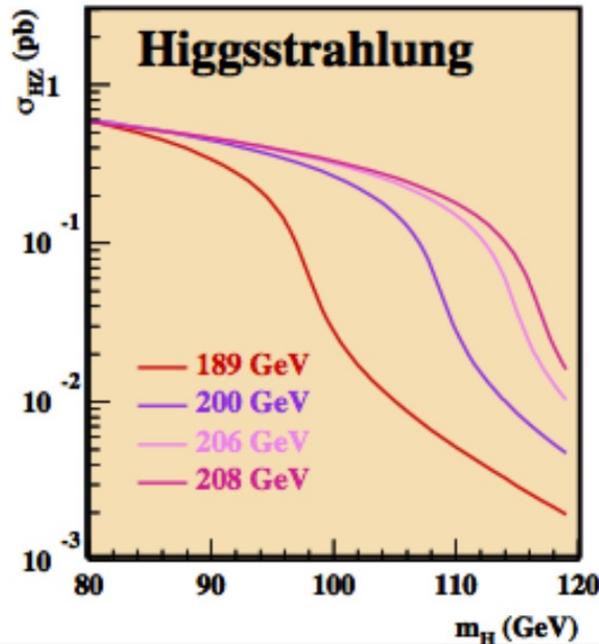

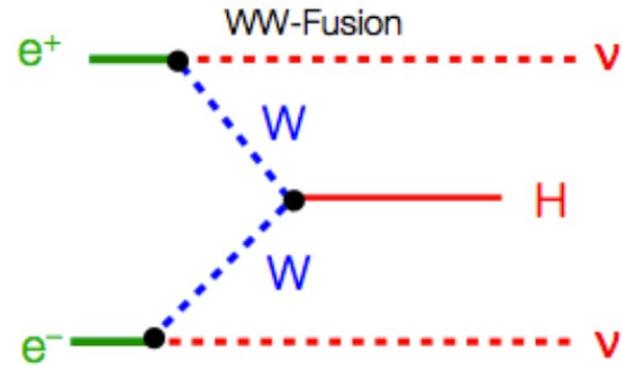

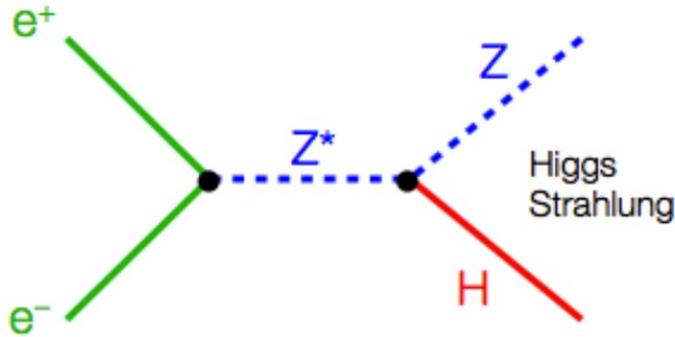

□  $m_H < 2m_b$ :  $H \rightarrow \tau^+\tau^-$  and  $c\bar{c}$  dominate;

□  $m_H > 2m_b$  up to  $1000 \text{ GeV}/c^2$ :

# Higher-mass Higgs production at LEP

# Summary of all Higgs candidates found at LEP

Invariant mass of all candidates

In total 17 candidates selected

- 15.8 background events expected

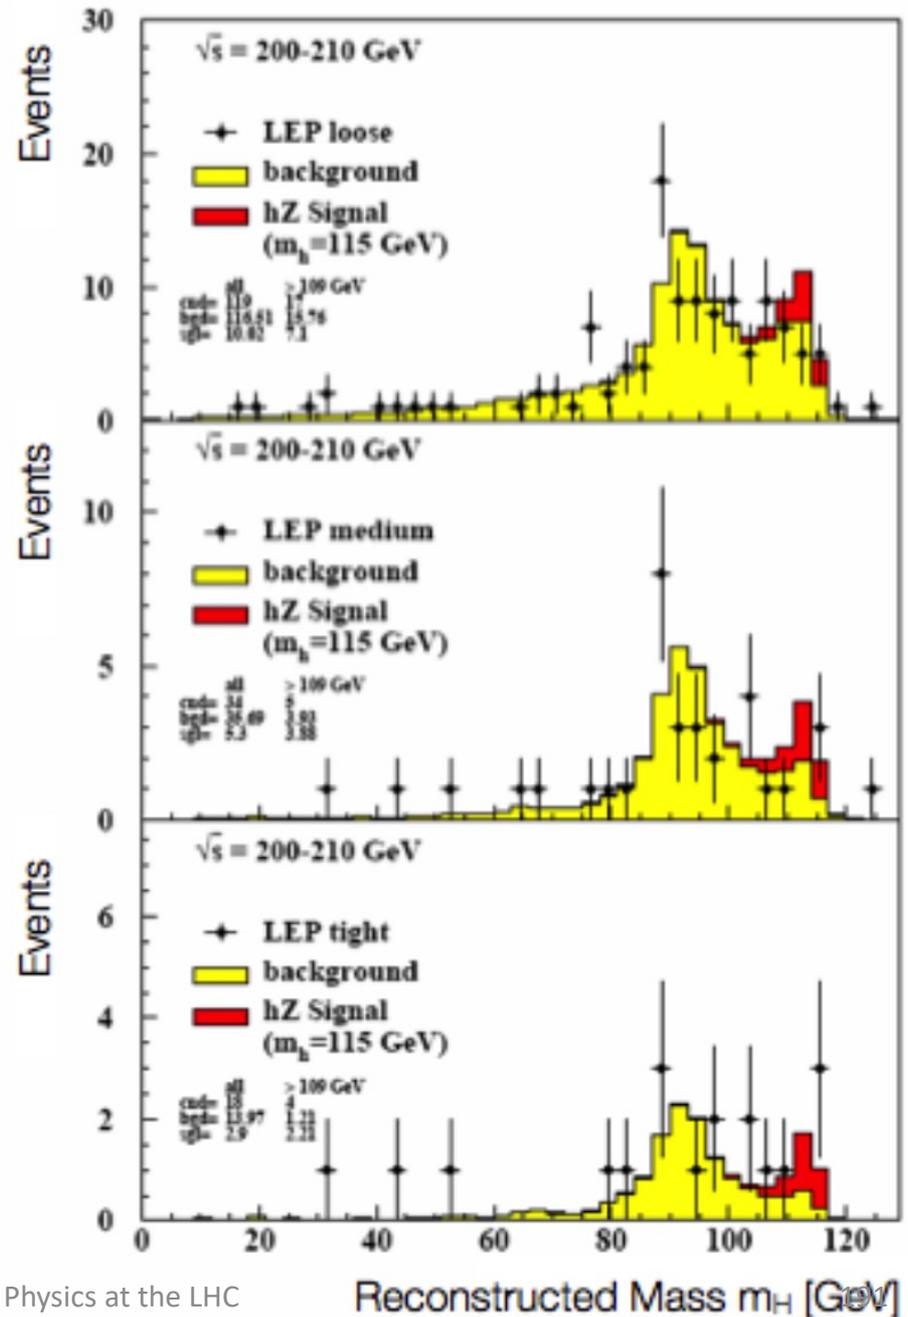

Expectation for  $m_H = 115$  GeV

- 8.4 events

Corresponding excess was not observed

Final verdict from LEP

$m_H > 114.4$  GeV @ 95% CL

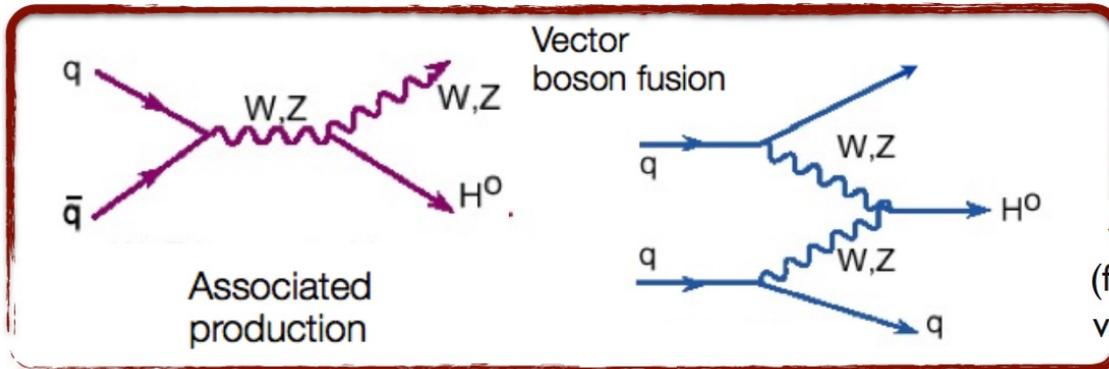

# Searches at the Tevatron

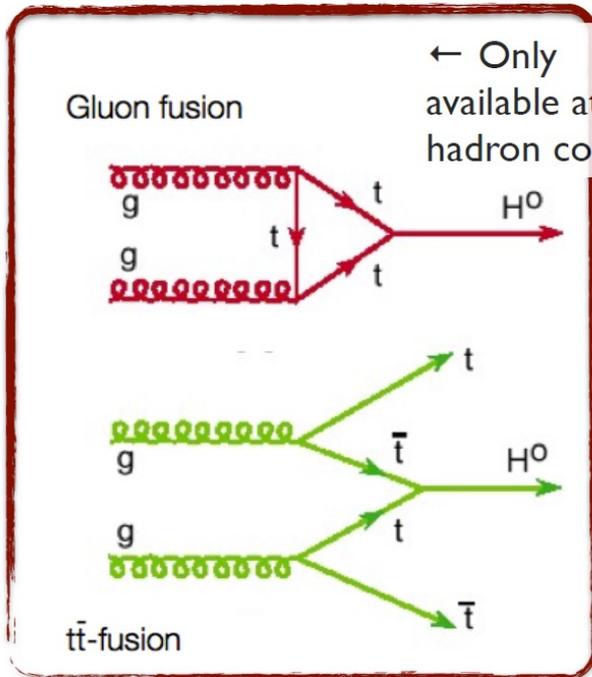

Proton-anti-proton collider at  $s^{1/2}=1.96$  TeV  
First superconducting accelerator  
Shutdown: 30 September 2011  
Almost  $10 \text{ fb}^{-1}$  of data for analysis

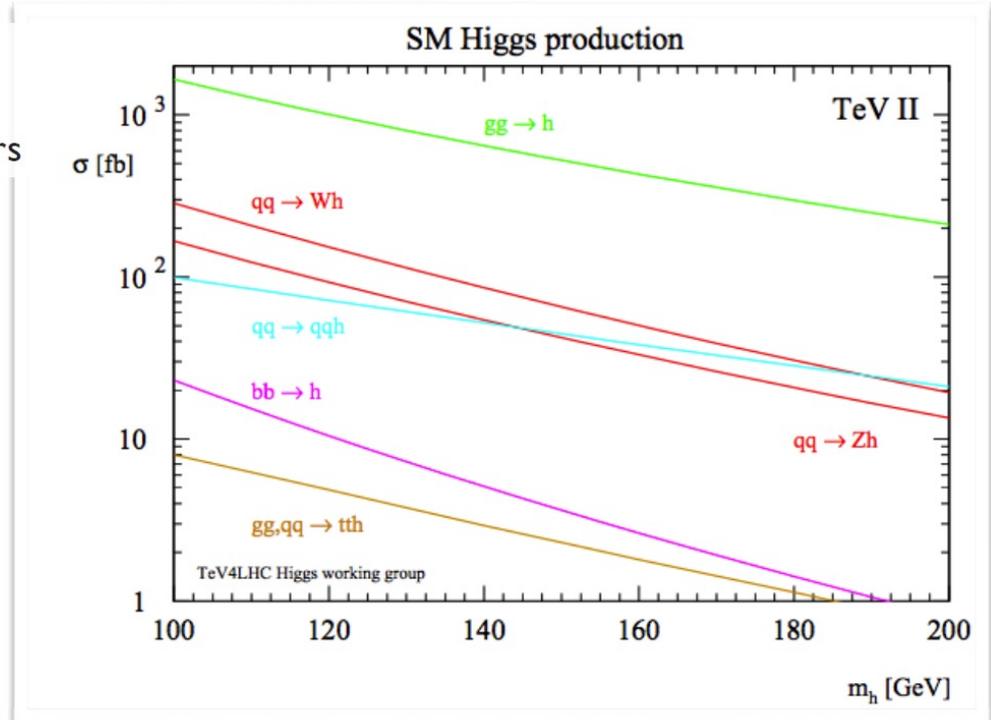

# Higgs production at the Tevatron

(fermion annihilation and vector boson scattering)

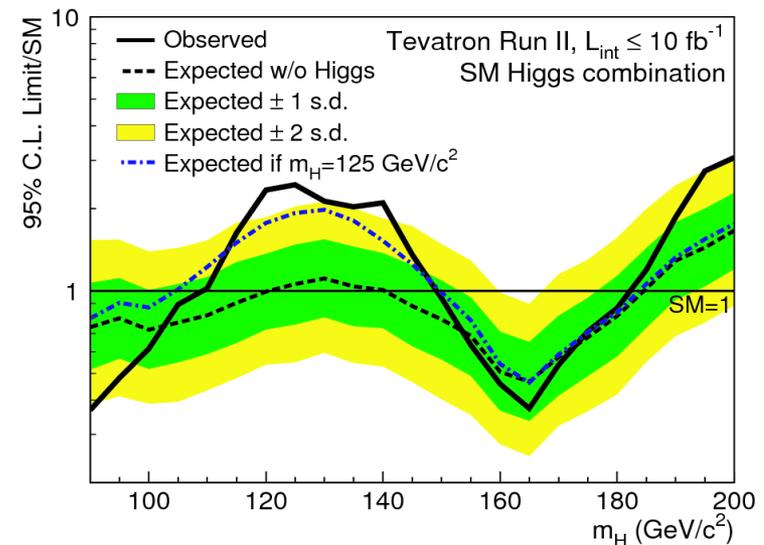

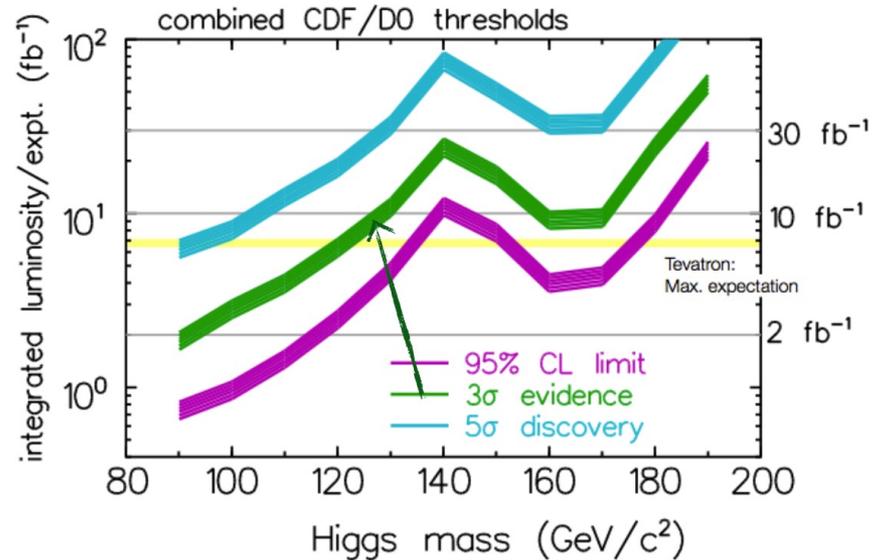

← Only available at hadron colliders

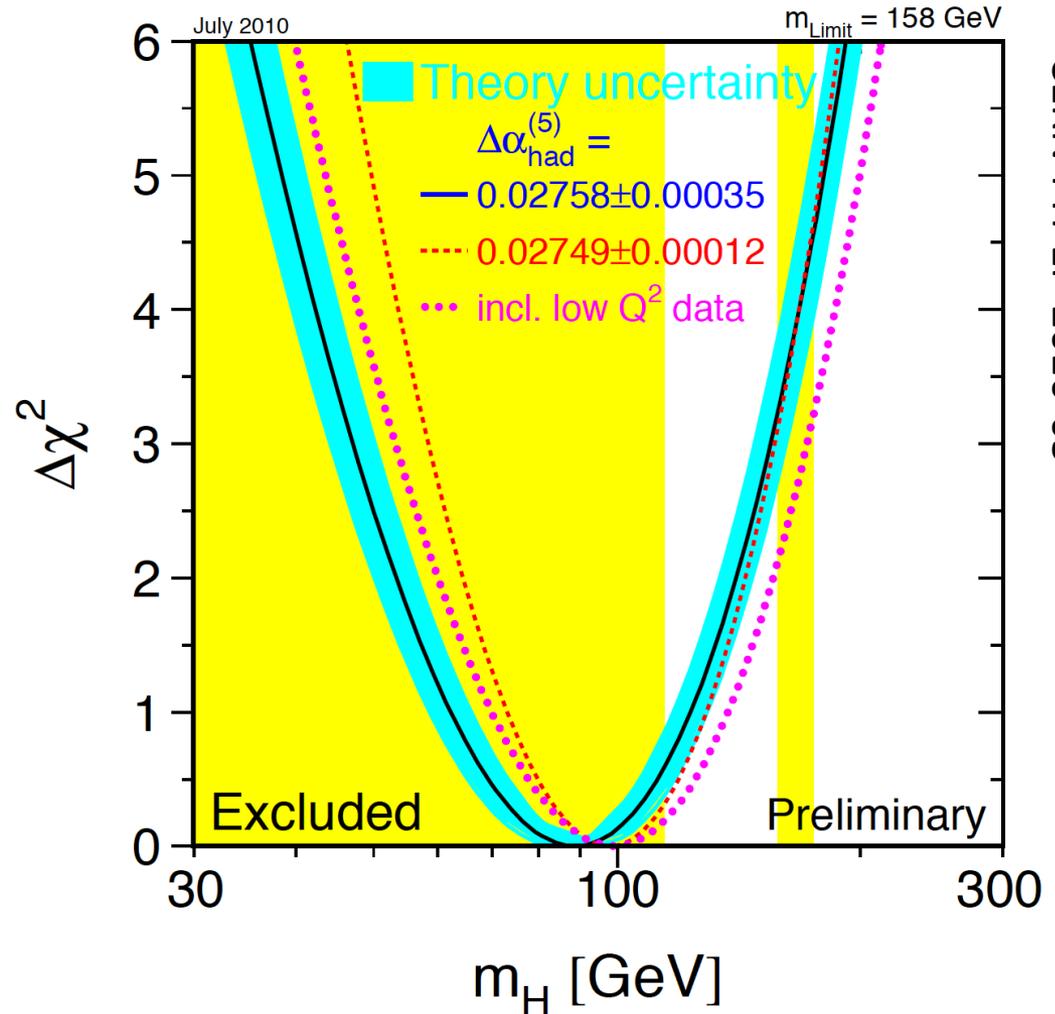

# The final stand of the Tevatron

- By the end of its lifetime, the Tevatron had very sophisticated analyses of a huge number of channels
- By that time the LHC was collecting data and analysing it very fast
- The CDF and D0 experiments obtained an excess of around 3 standard deviations in the mass range  $115 < M_H < 140$  GeV
- Not enough to claim discovery, but consistent with the LHC results

# LEP and Tevatron: the Blue Band Plot

- Decades of searches in several experiments...
- By July 2010:
  - LEP+Tevatron+SLD limits
  - Higgs excluded for  $m_h < 114.4$  GeV at 95% CL
  - Plus between 158 and 175 GeV

# Discovery at the LHC

Design (p-p run):

$\sqrt{s} = 14 \text{ TeV}$  (design)

$N_p = 1.2 \times 10^{11}$  p/bunch

2780 bunches

Peak L =  $1 \times 10^{34} \text{ cm}^{-2}\text{s}^{-1}$  (design)

$\beta^* = 55 \text{ cm}$

Run 1: 2009 – 2013  $\sqrt{s} = 7/8 \text{ TeV}$

Run 2: 2015 – 2018  $\sqrt{s} = 13 \text{ TeV}$

  - Other very difficult with higher rates ( $bb$ ,  $WW$ ,  $\tau\tau$ , ...)
- Access Higgs properties through combination of different channels

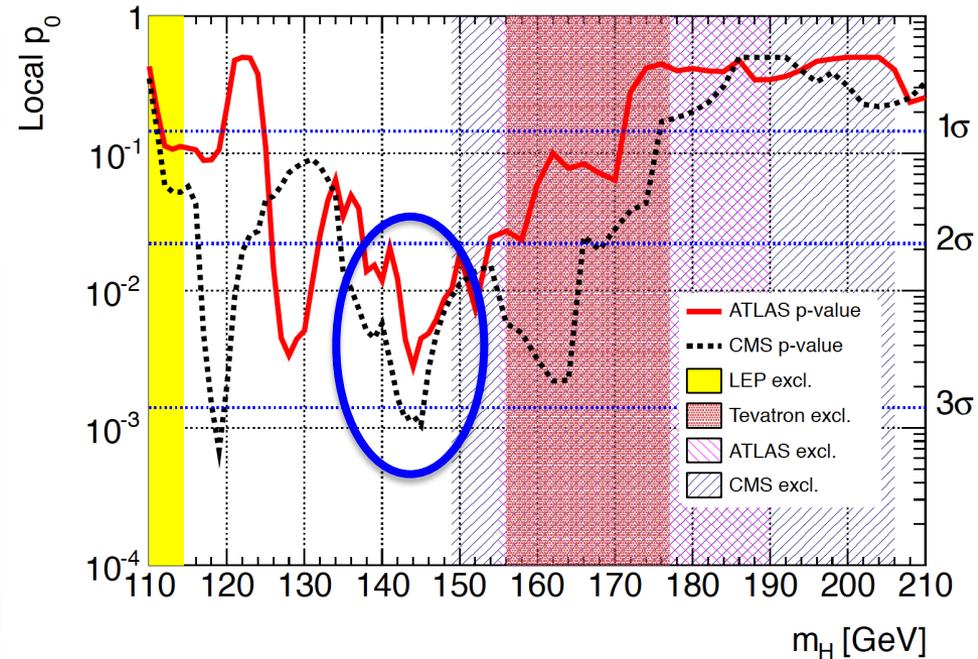

R. Gonalo - Physics at the LHC

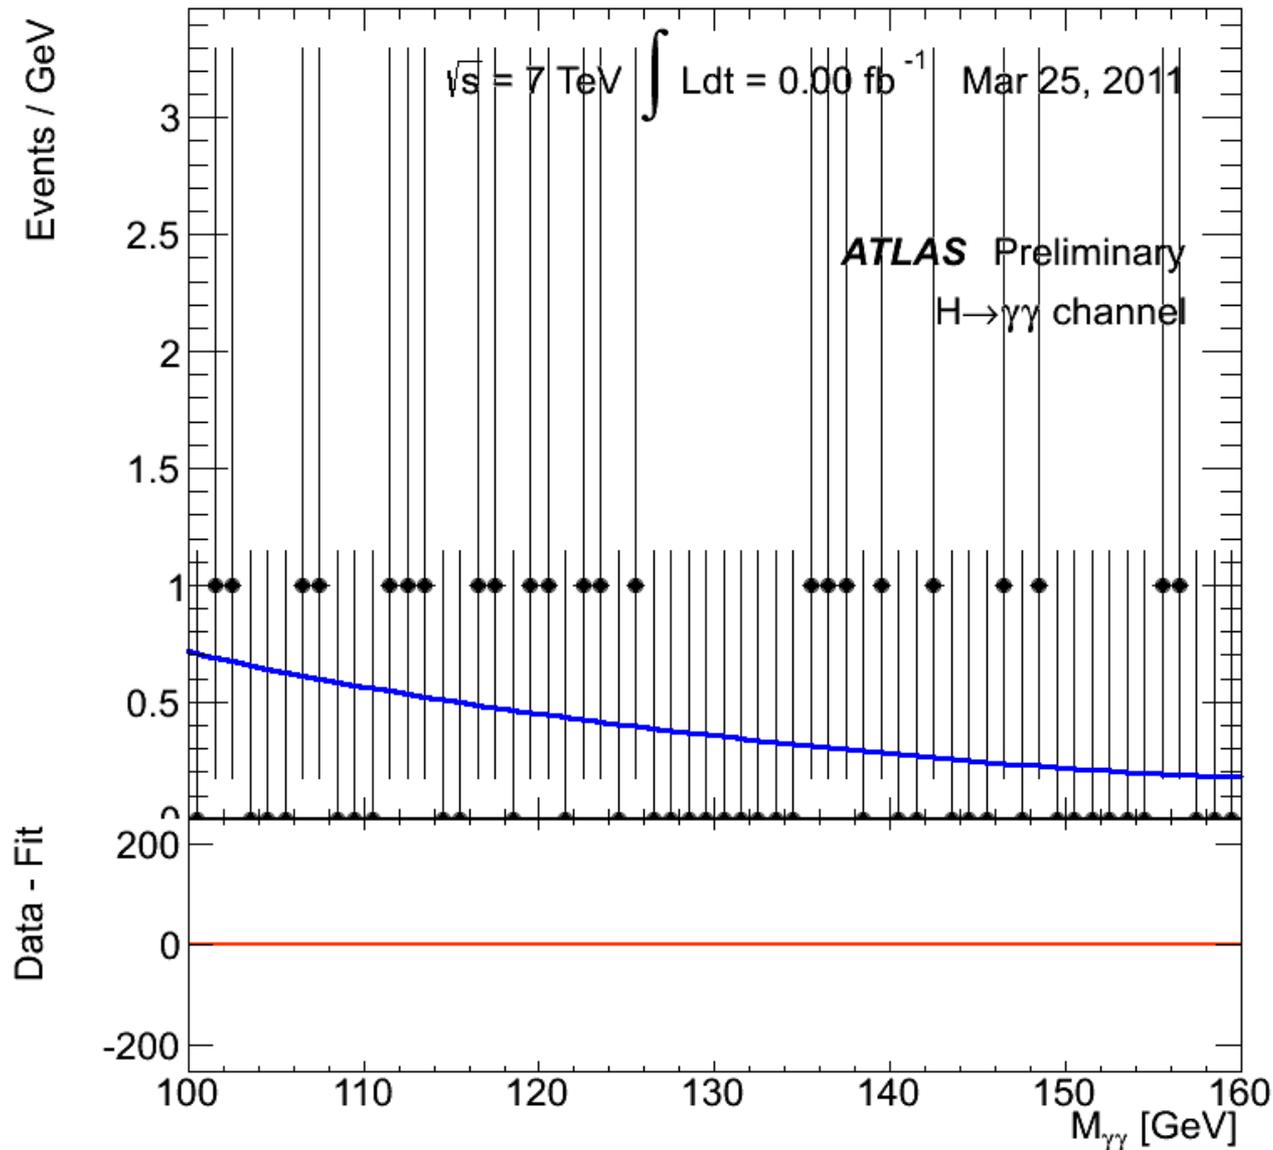

# It takes time to get it right

EPS-HEP 2011 conference [6]

# 2012: Descoberta do bóson de Higgs: $H \rightarrow \gamma\gamma$

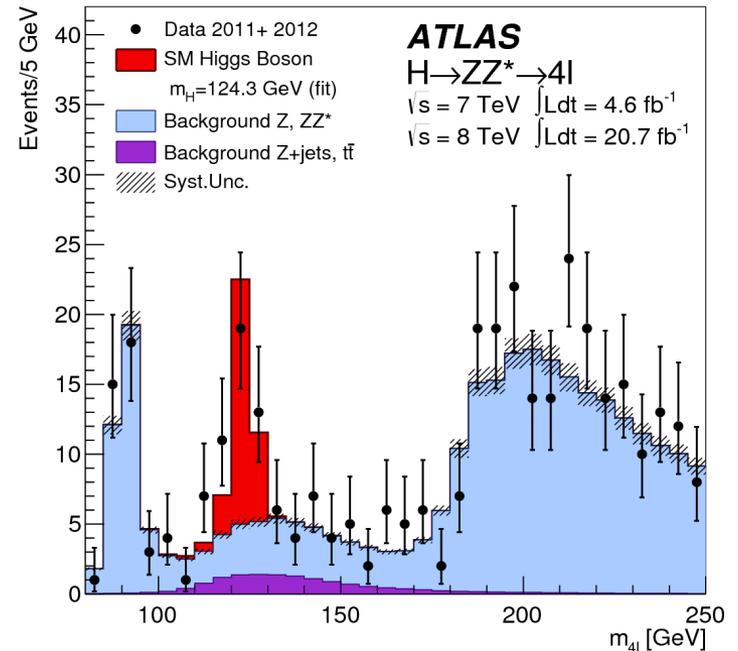

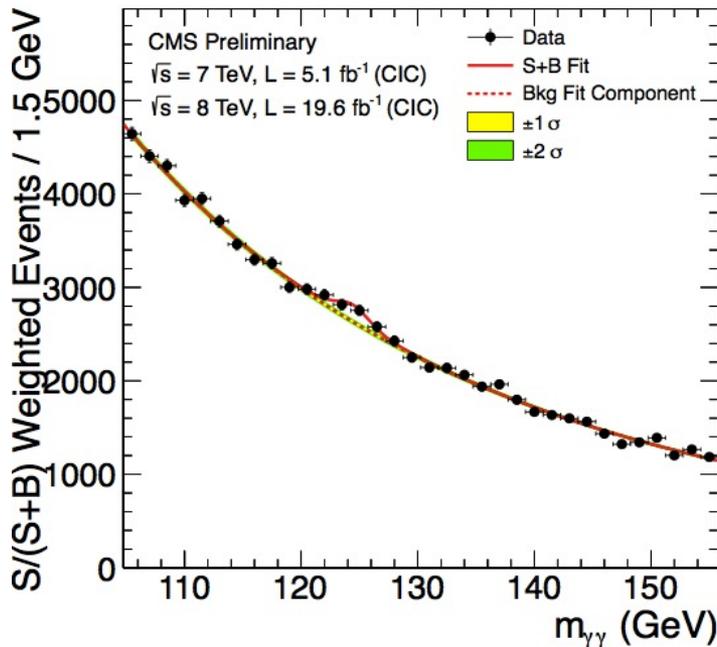

# Discovery channels

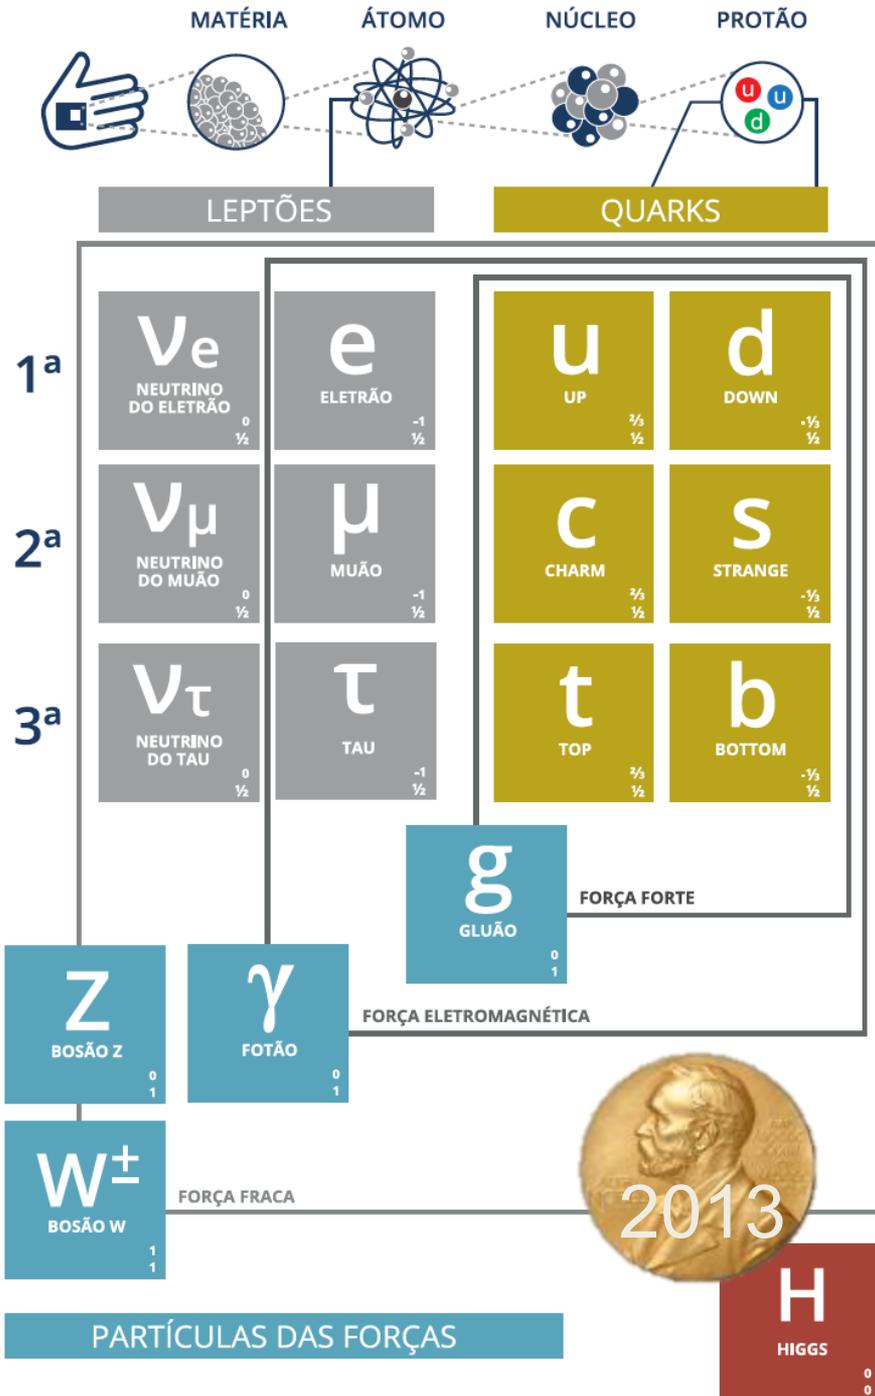

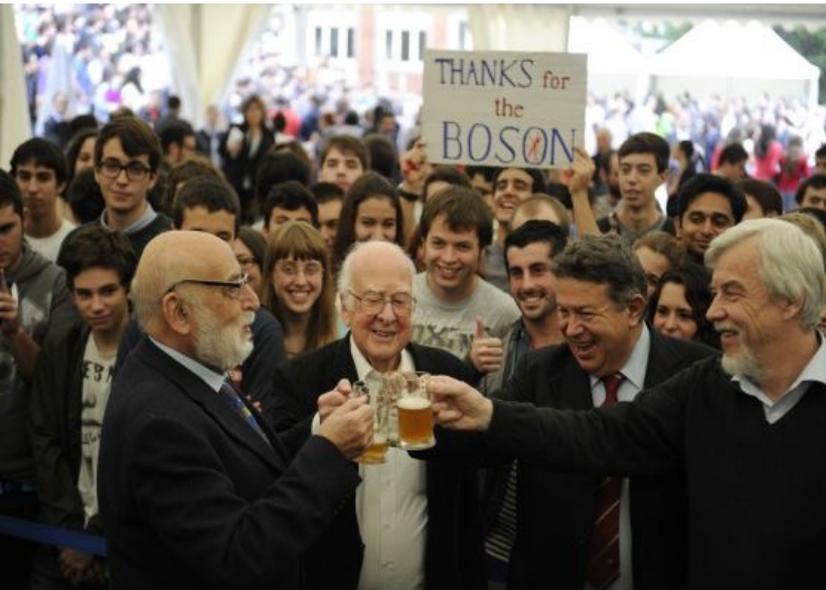

- Discovery was made in ATLAS and CMS with about  $5 \text{ fb}^{-1}$  of 7 TeV data and  $20 \text{ fb}^{-1}$  of 8 TeV data per experiment; several channels combined

$$h \rightarrow \gamma\gamma; h \rightarrow ZZ^* \rightarrow 4\ell; h \rightarrow WW^*; h \rightarrow \tau^+\tau^-; h \rightarrow b\bar{b}$$

- This means about 400 000 Higgs bosons produced in about 8 000 000 000 000 000 ( $8 \times 10^{15}$ ) proton collisions
  - Only about 4000 events with Higgs bosons contributed to the discovery

# A Descoberta do bóson de Higgs

# First observations of a new particle in the search for the Standard Model Higgs boson at the LHC

[www.elsevier.com/locate/physletb](http://www.elsevier.com/locate/physletb)

Two quotations from the experimental papers presented in this publication:

"... The search for the Higgs boson, the only elementary particle in the Standard Model that has not yet been observed, is one of the highlights of the Large Hadron Collider physics program."

- ATLAS Collaboration

"... The decay to two photons indicates that the new particle is a boson with spin different from one. The results presented here are consistent, ... with expectations for a standard model Higgs boson."

- CMS Collaboration

*Best wishes!  
Peter Higgs*

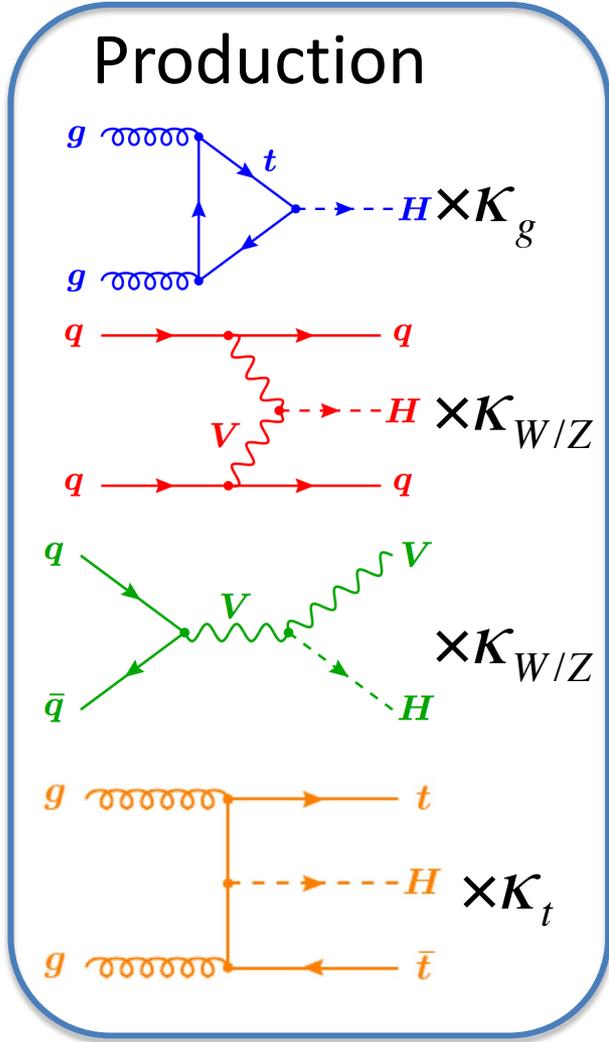

# What now?!

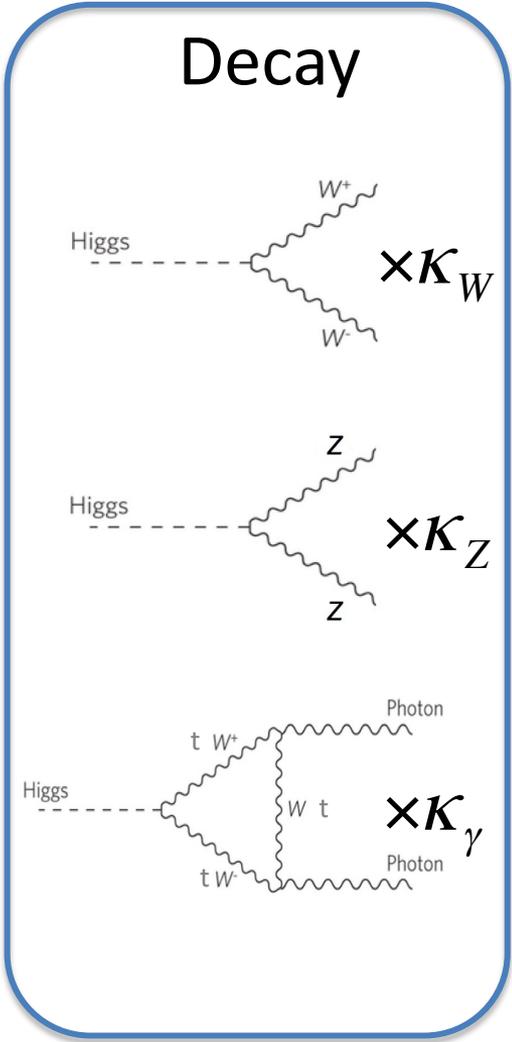

# Probing the 125 GeV Higgs

$$\kappa_i^2 = \sigma_i / \sigma_i^{SM} \quad \kappa_f^2 = \Gamma_f / \Gamma_f^{SM} \quad \mu = \frac{(\sigma \cdot BR)^{Obs.}}{(\sigma \cdot BR)^{SM}} = \kappa_i^2 \cdot \kappa_f^2$$

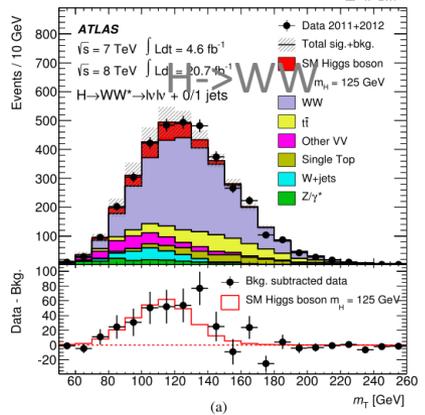

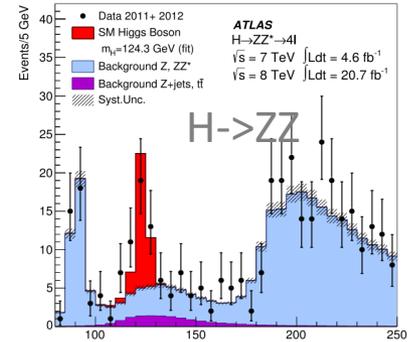

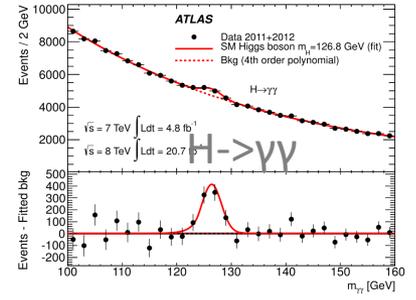

**X**

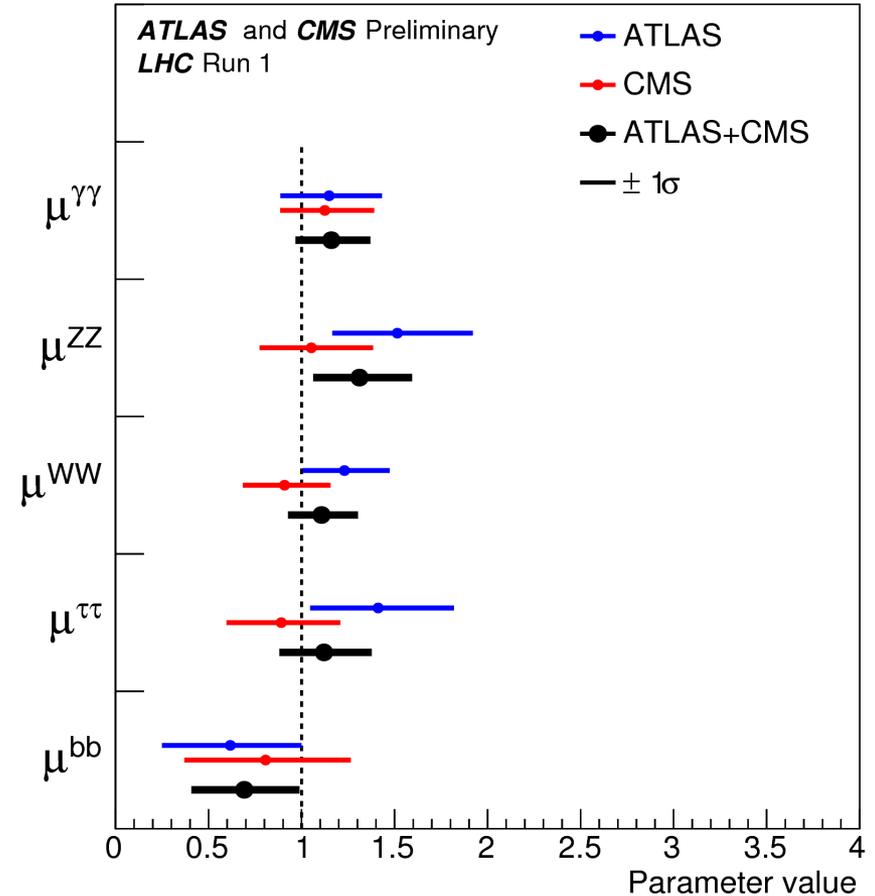

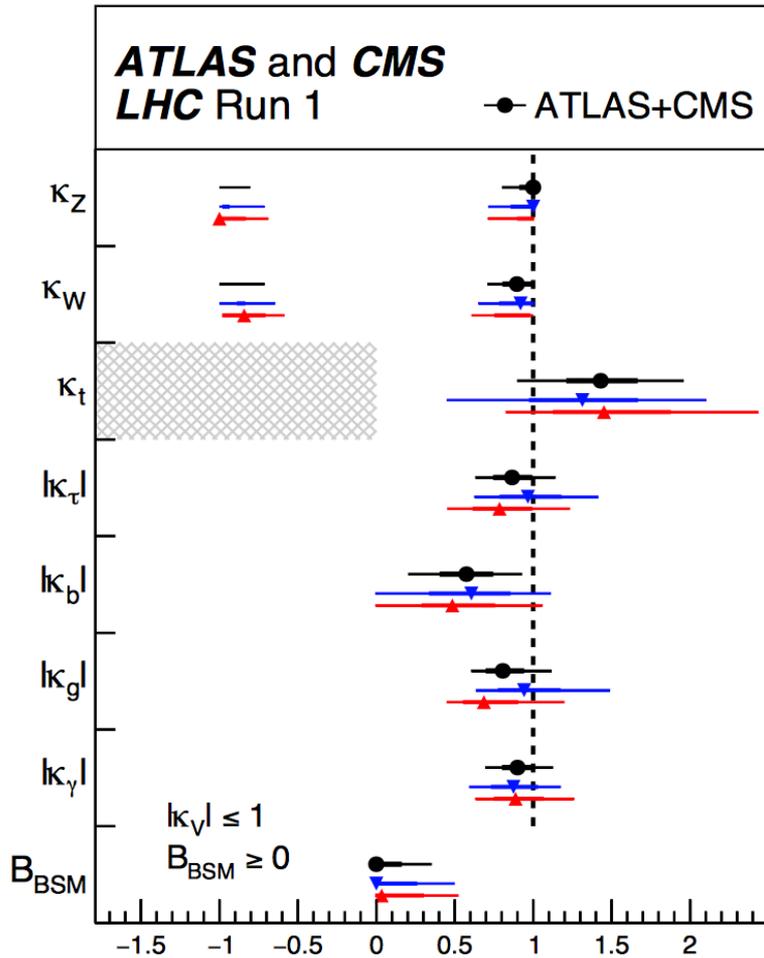

FIT

Backgrounds +

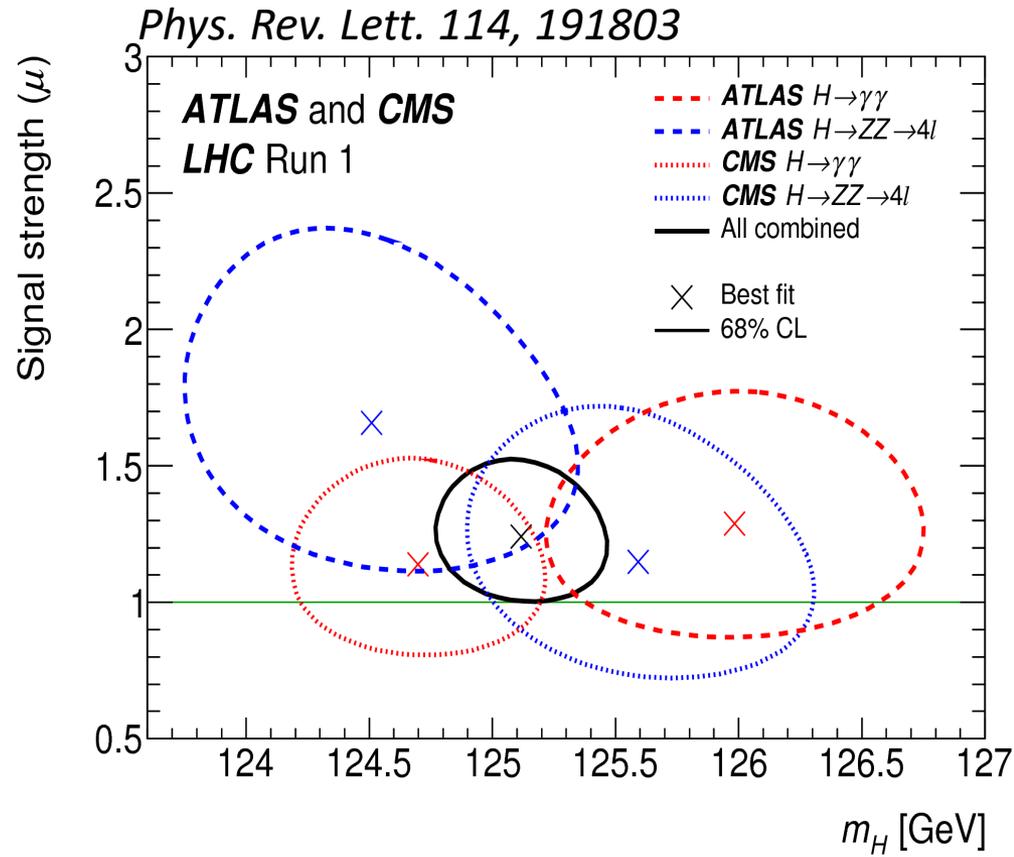

# Signal strength measurements

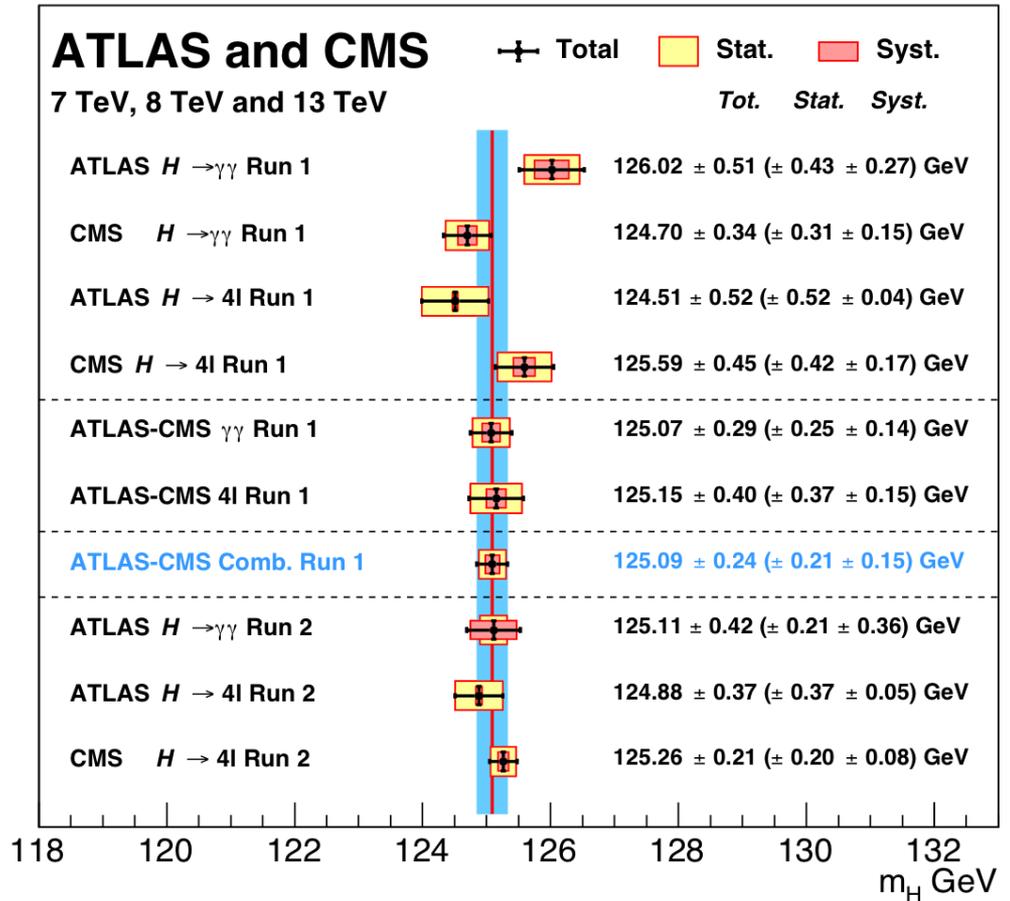

# Higgs boson mass

- Mass: around 125 GeV  
**Was the only unknown SM parameter** 😊
- For a while, different mass values were being measured in ATLAS and CMS, and in different channels
- Numbers evolved with accumulated statistics

# Higgs boson mass

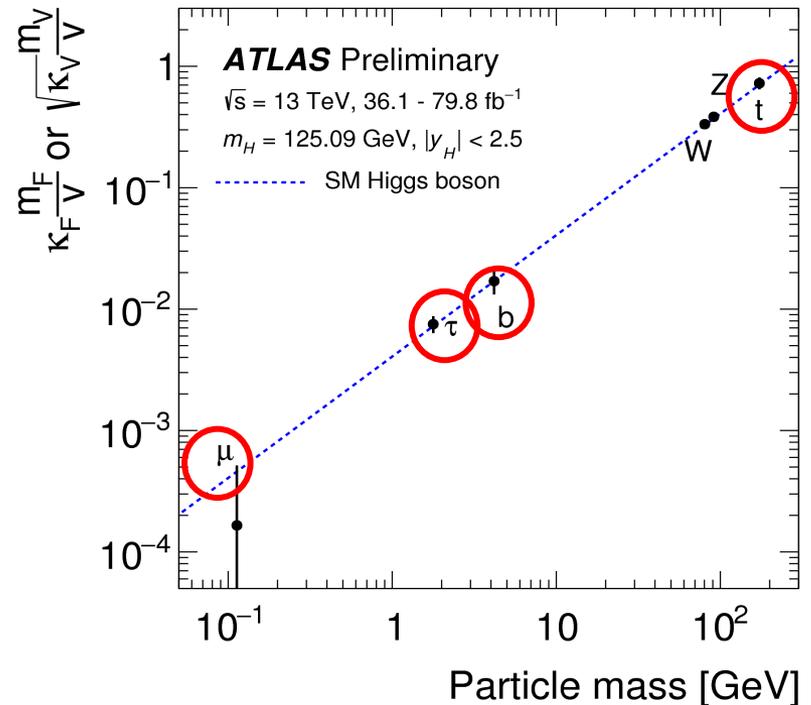

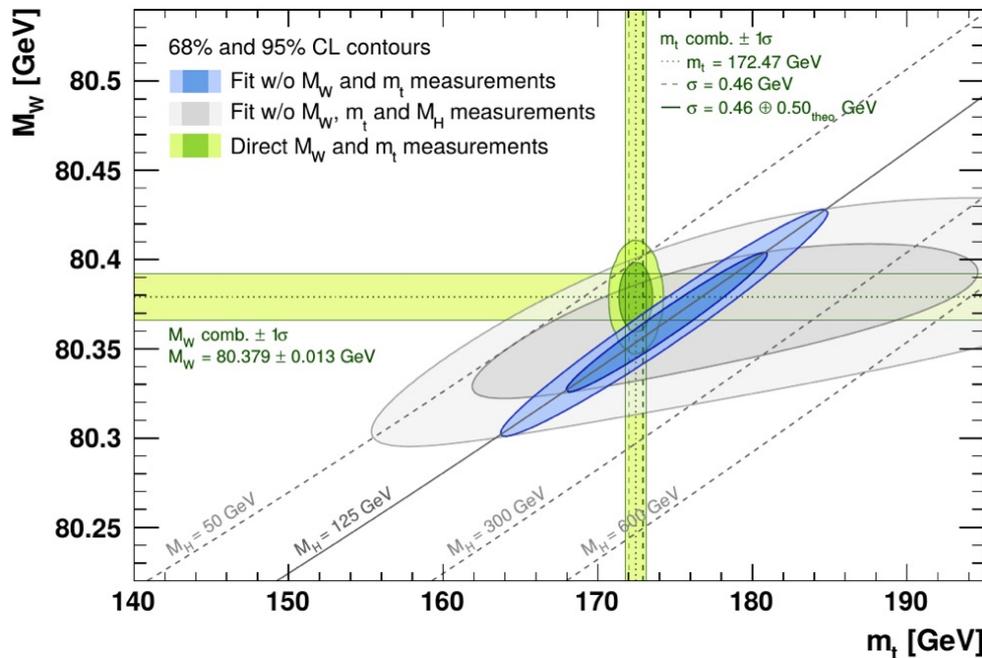

- Mass measurement from
  - $H \rightarrow ZZ^* \rightarrow 4l$
  - $H \rightarrow \gamma\gamma$
- Precision at the permille level achieved

# Exploring the electroweak scale

- Precision measurements of  $m_W$ ,  $m_t$ ,  $m_H$  are stringent tests of the SM at the EW scale
  - E.g. excluding measured  $m_H$ , global EW fit gives  $m_H = 90 \pm 21$  GeV (1.7  $\sigma$  tension) driven in part by  $m_{\text{top}}$

arXiv:1803.01853

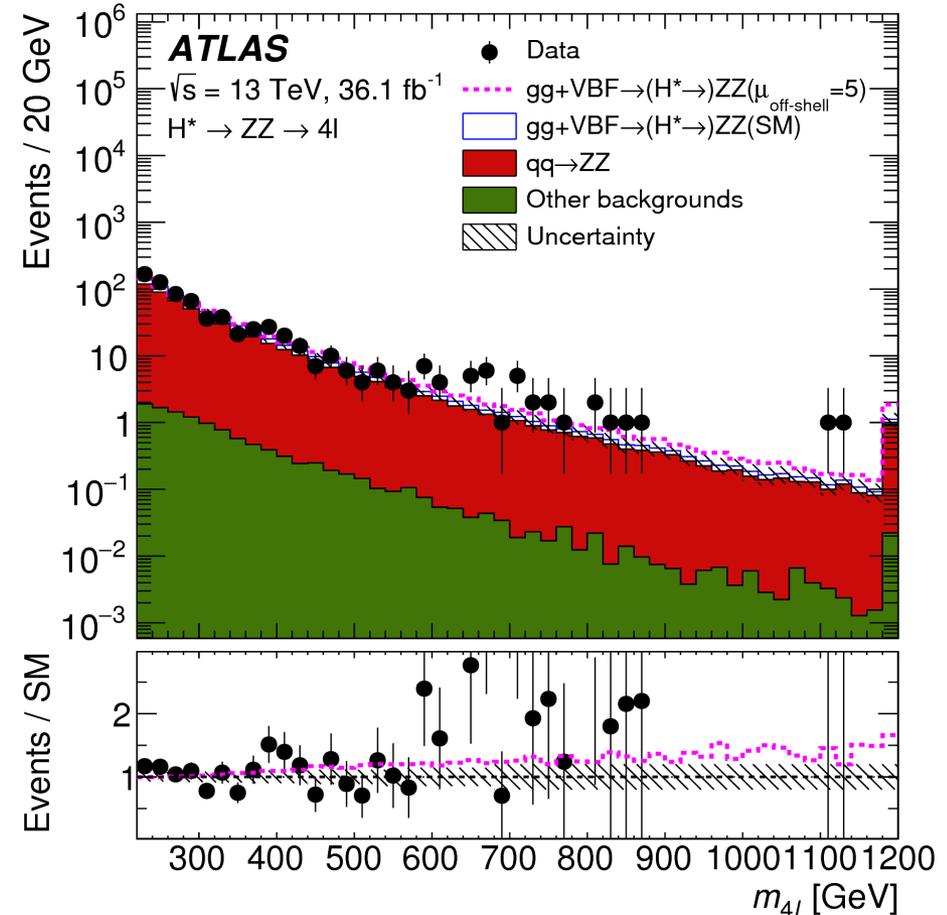

# Higgs boson width

- SM Higgs width  $\Gamma_H \sim 4.1$  MeV
  - Too small to be measured directly
  - Best direct limit from CMS:
    - $\Gamma_H < 1.1$  GeV @ 95% CL
- Off-shell Higgs production sensitive(\*) to  $\Gamma_H$

$$\frac{\mu_{\text{off-shell}}}{\mu_{\text{on-shell}}} = \frac{\kappa_{g,\text{off-shell}}^2 \cdot \kappa_{Z,\text{off-shell}}^2}{\kappa_{g,\text{on-shell}}^2 \cdot \kappa_{Z,\text{on-shell}}^2} \frac{\Gamma_H}{\Gamma_H^{SM}}$$

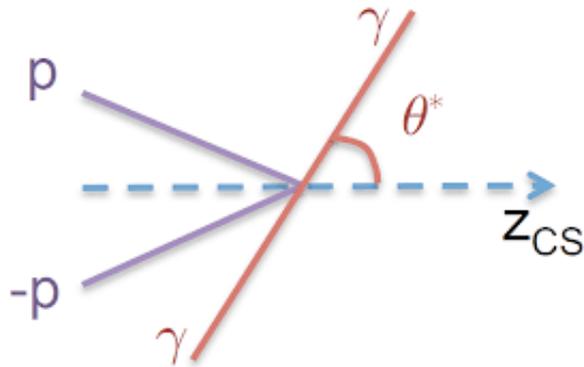

- ATLAS measurement:
  - $pp \rightarrow H \rightarrow ZZ \rightarrow 4l$  and  $ZZ \rightarrow 2l2\nu$
  - $m(H) > 2 m(Z)$
  - 36.1 fb<sup>-1</sup> of 13 TeV data
  - Observed (expected) limit:
    - $\Gamma_H < 14.4$  (15.2) MeV

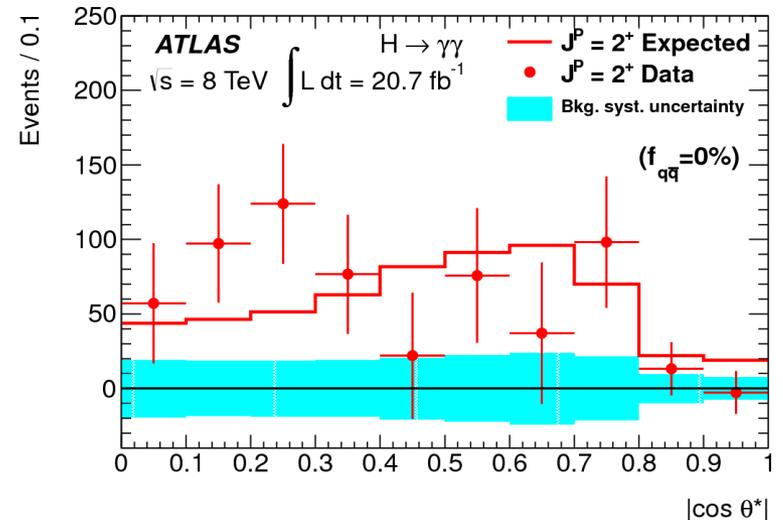

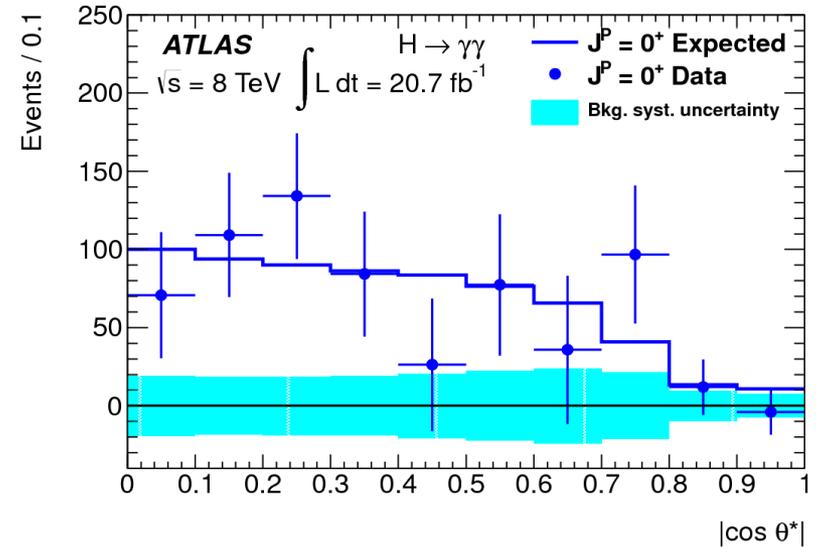

(\*) Assume interference term with  $gg \rightarrow ZZ$  proportional to  $K_{g,\text{off-shell}} \cdot K_{Z,\text{off-shell}}$

# Measuring the Higgs Spin

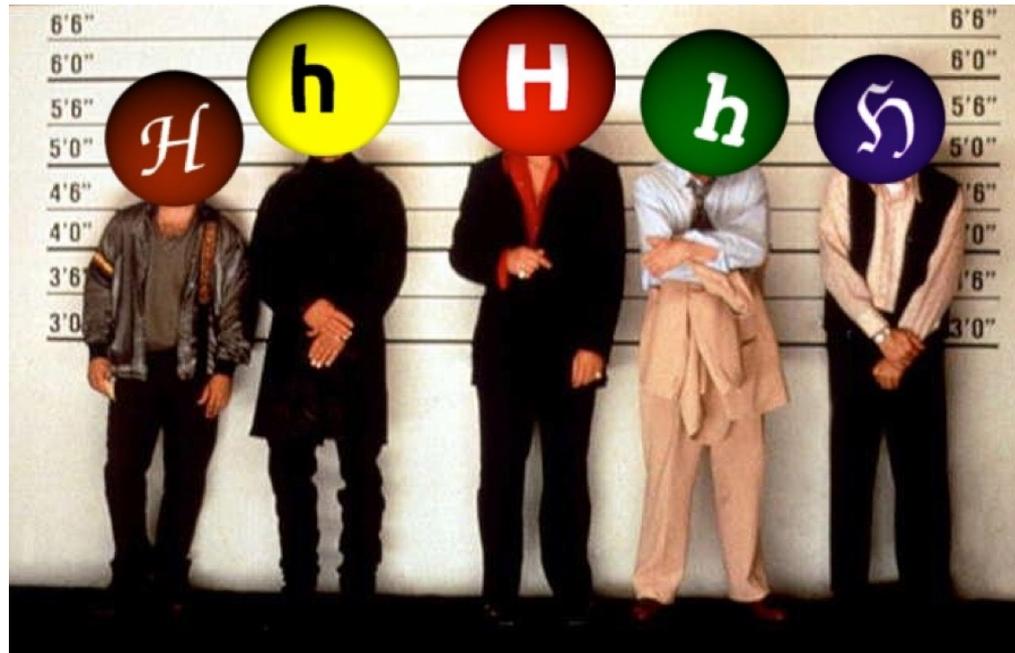

- Polar angle  $\theta$  in the rest frame of the diphoton system (Collins-Soper frame)

$$|\cos \Theta^*| = \frac{|\sinh(\Delta\eta^{\gamma\gamma})|}{\sqrt{1 + \frac{p_{T,\gamma\gamma}^2}{m_{\gamma\gamma}^2}}} \frac{2p_T^{\gamma_1} p_T^{\gamma_2}}{m_{\gamma\gamma}^2}$$

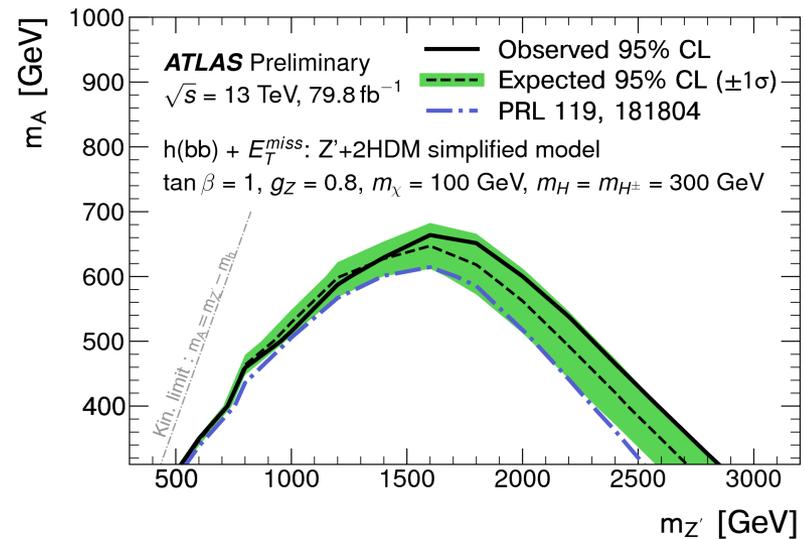

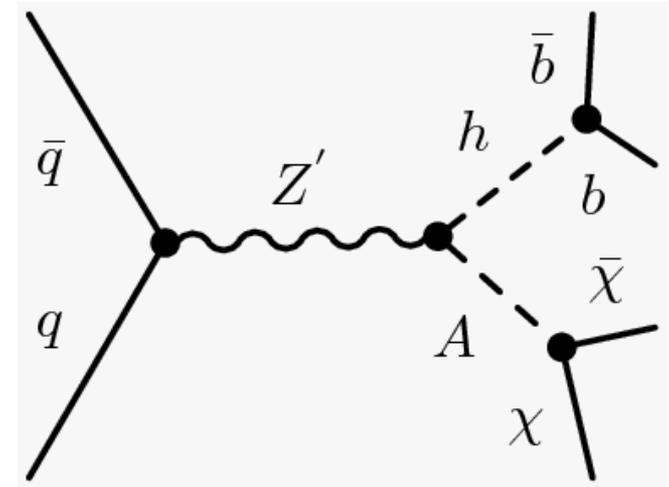

# Casting a wider net

# Higgs + Dark Matter

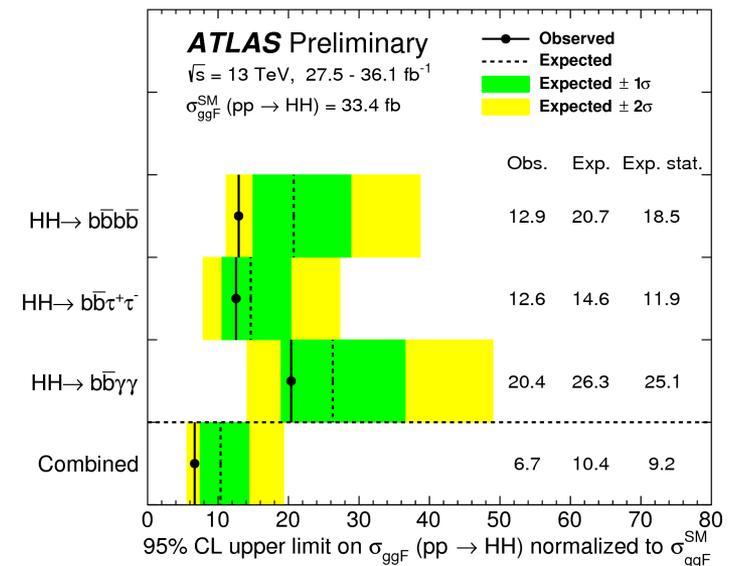

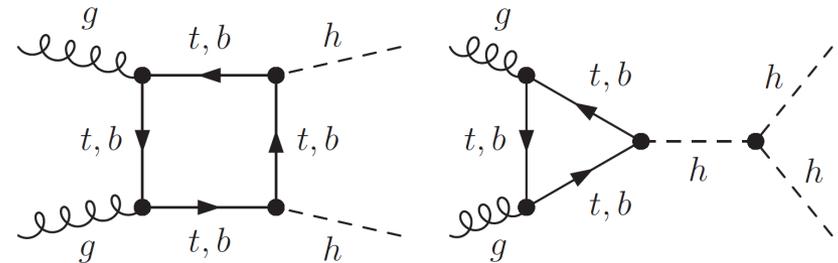

- Used  $79.8 \text{ fb}^{-1}$  of 13 TeV data
  - High  $E_T^{\text{miss}}$  ( $>150 \text{ GeV}$ ) and b-tagging to suppress backgrounds
  - Reconstruct b-jets as 2 small jets or merged variable-radius (VR) track jets
- Signal benchmark: Type-II 2HDM +  $U(1)_{Z'}$  symmetry (Z'-2HDM)
- Main backgrounds:  $t\bar{t}$ ,  $W/Z$ +jets
- Excluded region in  $m_A - m_{Z'}$  plane

# Triple Higgs coupling

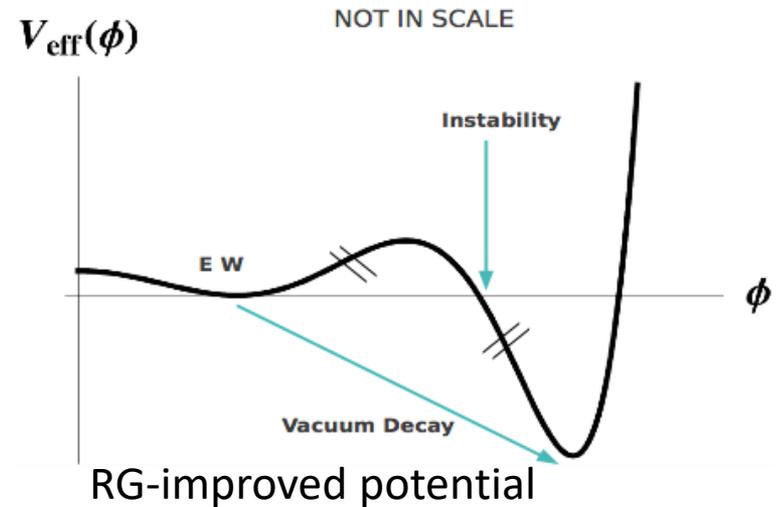

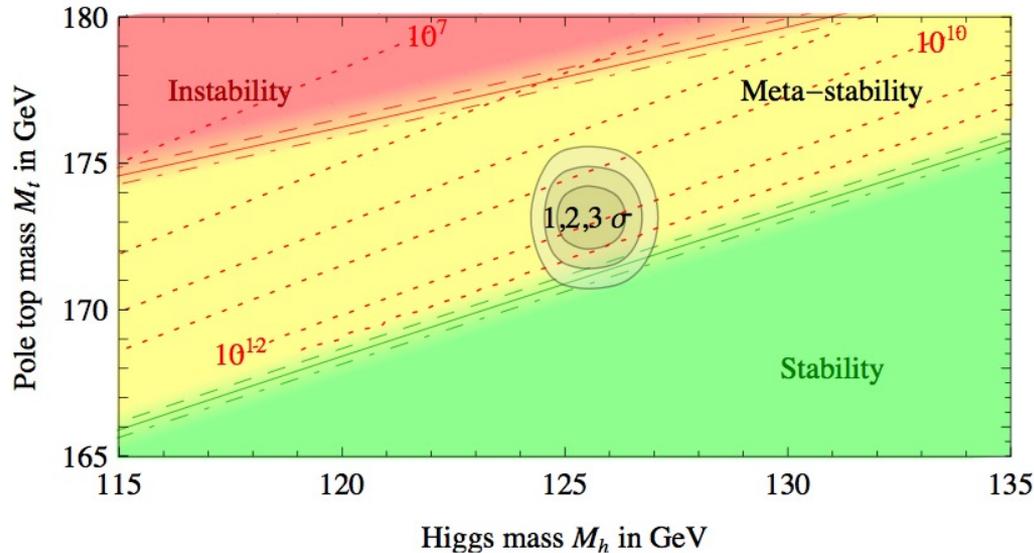

- The triple Higgs coupling  $\lambda_{HHH}$  can be probed through di-Higgs production
- Very suppressed in SM!
  - Negative interference between LO diagrams
  - Cross section 1500x less than ggF
- Wide range of decay BR and channel purity
- $bb\tau\tau$  analysis:
  - Used  $36 \text{ fb}^{-1}$  of 13 TeV data
  - Final state BR( $bb\tau\tau$ )=7%
  - Non-Resonant 95% CL limit:  
 $\mu < 12.7$  observed (**14.8 expected**)
- **Combination: at  $\approx 10 \times$  SM sensitivity**  
– with 3% of the HL-LHC luminosity analyzed

$$V(\phi) = \mu^2 \phi^\dagger \phi + \lambda (\phi^\dagger \phi)^2$$

Di-Higgs combination plot [here](#)

# A bit of fun...

- What if...
  - At higher orders, Higgs potential doesn't have to be stable
  - Depending on  $m_t$  and  $m_H$  second minimum can be lower than EW minimum  $\Rightarrow$  tunneling between EW vacuum and true vacuum?!
- “For a narrow band of values of the top quark and Higgs boson masses, the Standard Model Higgs potential develops a shallow local minimum at energies of about  $10^{16}$  GeV, where primordial inflation could have started in a cold metastable state”, I. Masina, arXiv:1403.5244 [astro-ph.CO]
  - See also: V. Brachina, Moriond 2014 (Phys.Rev.Lett.111, 241801 (2013)), G. Degraasi et al, arXiv:1205.6497v2; R.Contino, Workshop sulla fisica p-p a LHC, 2013

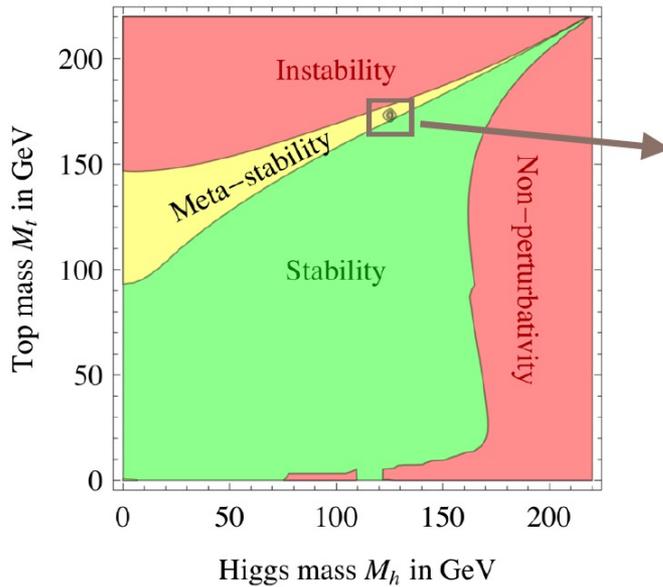

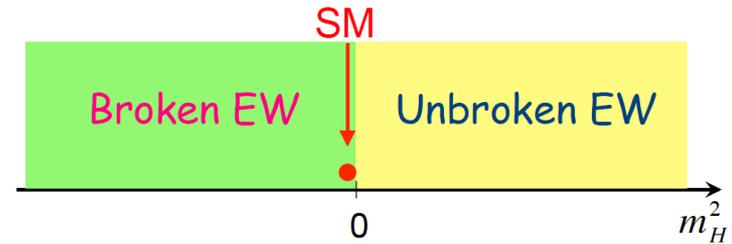

# The universe seems to live near a critical condition

JHEP 1208 (2012) 098

Why?!

Explained by underlying theory?

Anthropic principle?

# Higgs @ LIP ATLAS Group

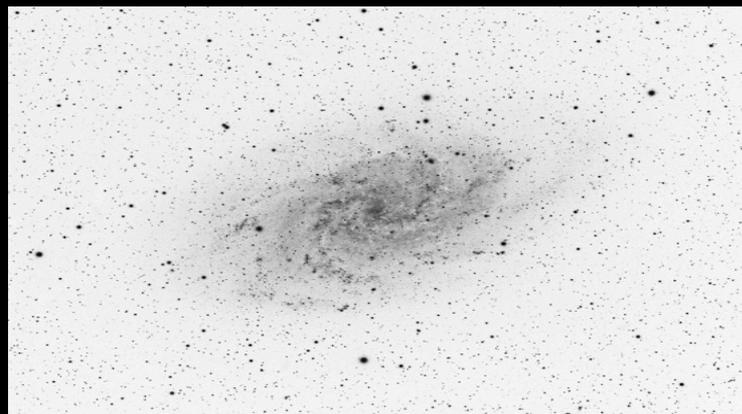

- Exploring Higgs couplings to heavy quarks
- Less well known...  
Much more space for surprises!
- New physics effects may show up already at leading order

2018: Hbb and Htt couplings demonstrated  
2020: CP of ttH coupling in ttH, H->γγ  
2022: ttH, H->bb fiducial cross section  
2022: Preliminary results for CP of ttH coupling studied in ttH, H->bb

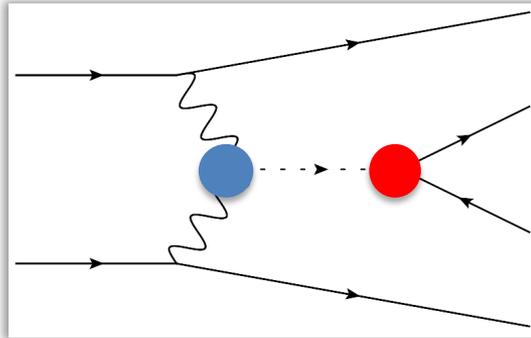

# ttH CP measurement

- Sakharov conditions for a matter-dominated universe require CP violation
- Known CP-violating processes:
  - From complex phases in CKM-matrix - quark mixing
  - Maybe in PNMS-matrix as well - neutrino mixing
- BUT: insufficient, by orders of magnitude
- CP violation in Higgs sector?
  - Possible in some models with extended Higgs sector (e.g. some 2HDMs)
  - Need **mixing** of scalar (CP-even) and pseudo-scalar (CP-odd) Higgs states
- What do we know about Higgs CP properties?
  - In the SM, Higgs scalar is a CP eigenstate with  $J^{CP} = 0^{++}$
  - Pure  $J^P = 0^-$  hypothesis for observed Higgs boson was ruled out in Run 1
  - But a **large** CP-odd admixture is not ruled out

# How to search for a CP-odd admixture?

- Effect of CP-odd components on **bosonic couplings** parametrized as expansion with higher order terms suppressed by powers of scale of new physics  $\Lambda$
- Could explain why a CP-odd admixture has not been seen

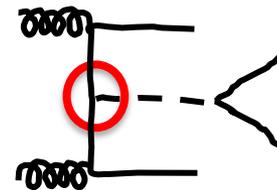

- **Fermionic couplings** are affected at tree level
- Mixing angle  $\alpha$  between CP-even and CP-odd coupling components
- More notable for heavier fermions due to enhanced coupling

$$\mathcal{L}_{VVH} = \mathcal{L}_{VVH,SM} + \frac{1}{\Lambda^2} c \phi \tilde{V}_{\mu\nu} V^{\mu\nu} + \dots$$

$$\mathcal{L}_{ffH} = \kappa'_f y_f \phi \bar{\psi}_f (\cos \alpha + i \gamma_5 \sin \alpha) \psi_f$$

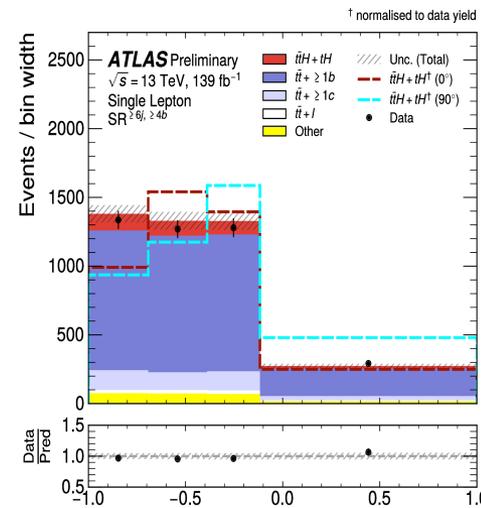

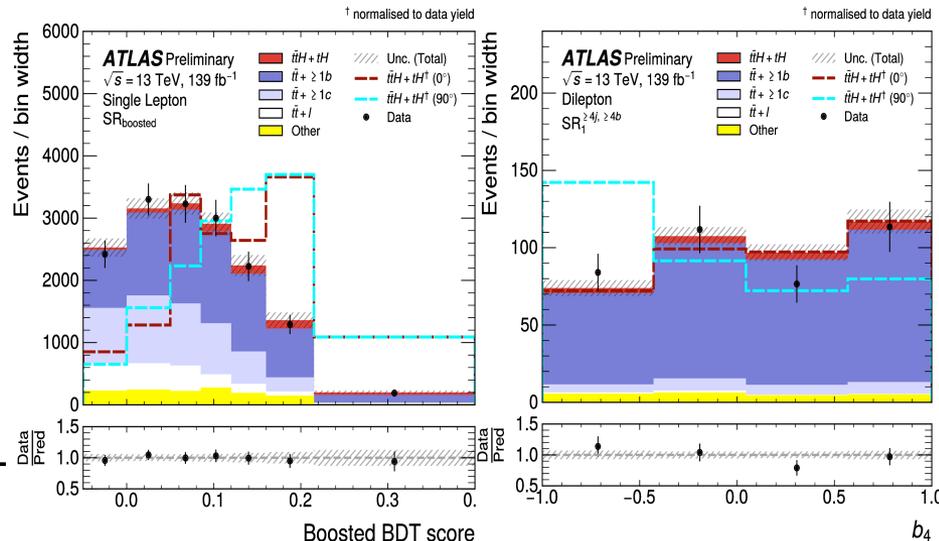

# H-top Coupling in ttH/tH production

- Calculate CP-sensitive observables  $b_2$  and  $b_4$  from top-quark 3-momenta
- Use different observables in combined fit depending on region

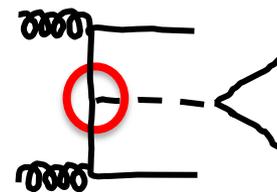

$$b_2 = \frac{(\vec{p}_1 \times \hat{n}) \cdot (\vec{p}_2 \times \hat{n})}{|\vec{p}_1| |\vec{p}_2|}$$

$$b_4 = \frac{p_1^z p_2^z}{|\vec{p}_1| |\vec{p}_2|}$$

Channel (PSR)	Final SRs and CRs	Classification BDT selection	Fitted observable
Dilepton (PSR $^{\ge 4j, \ge 4b}$ )	CR $_{no-reco}^{\ge 4j, \ge 4b}$	-	$\Delta\eta_{\ell\ell}$

# H-top Coupling in $t\bar{t}H/tH$ production

Simultaneous fit in all regions

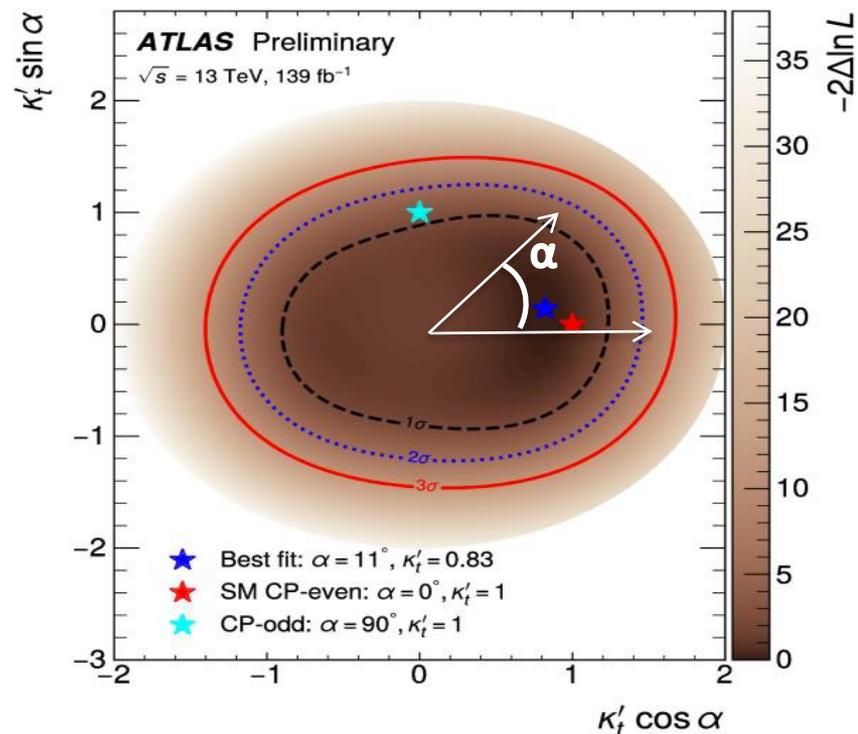

- $\mu = 0.83^{+0.30}_{-0.46}$
- $\alpha = 11^\circ^{+55}_{-77}$

Expected:

- $\mu = 1.0^{+0.25}_{-0.27}$
- $\alpha = 0^\circ^{+49}_{-50}$
- Pure CP-odd ( $\alpha = 90^\circ$ ) disfavoured at **1.2  $\sigma$**

Complementary to previous  $t\bar{t}H(H \rightarrow \gamma\gamma)$  analysis:

- [Phys. Rev. Lett. 125 \(2020\) 061802](#)
- Pure CP-odd ( $\alpha = 90^\circ$ ) excluded at **3.9  $\sigma$**
- Limit on  $|\alpha| < 43^\circ$  at 95% C.L.

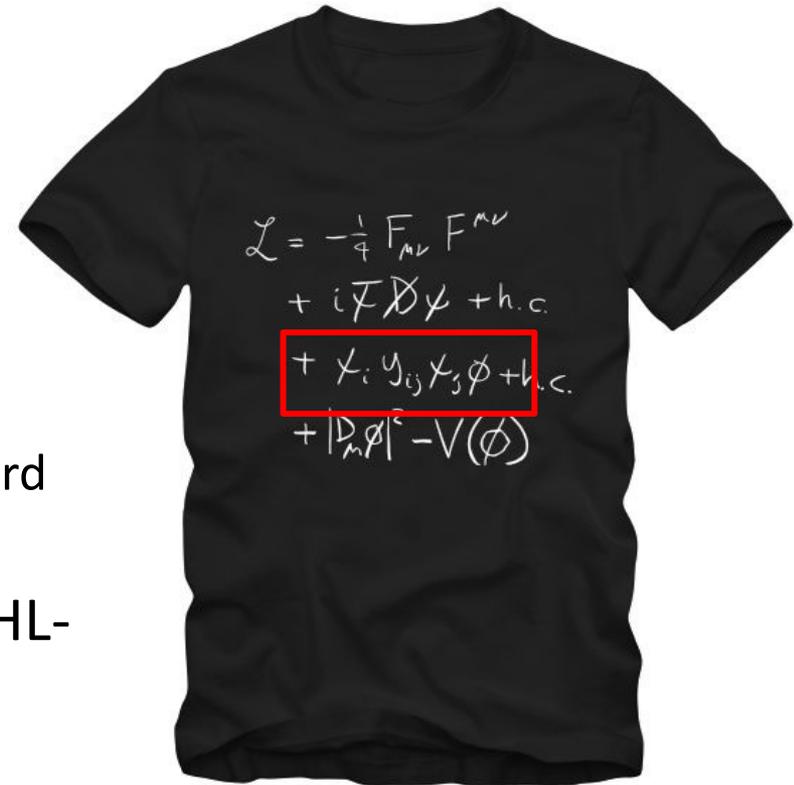

$$\mathcal{L}_{t\bar{t}H} = -\kappa'_t y_t \phi \bar{\psi}_t (\cos \alpha + i\gamma_5 \sin \alpha) \psi_t$$

# Summary

- Higgs sector measurements look SM-like so far
- **But there is new physics out there!**
- The Higgs is:
  - The only fundamental scalar
  - Connected to EW symmetry breaking
  - A great window to look beyond the Standard Model
- And we have only collected  $\approx 5\%$  of all HL-LHC data!

**Watch this space!**

T H E T R U T H I S O U T T H E R E .

**STAY TUNED!**

THE TRUTH IS OUT THERE.

# H-top Coupling in ttH/tH production

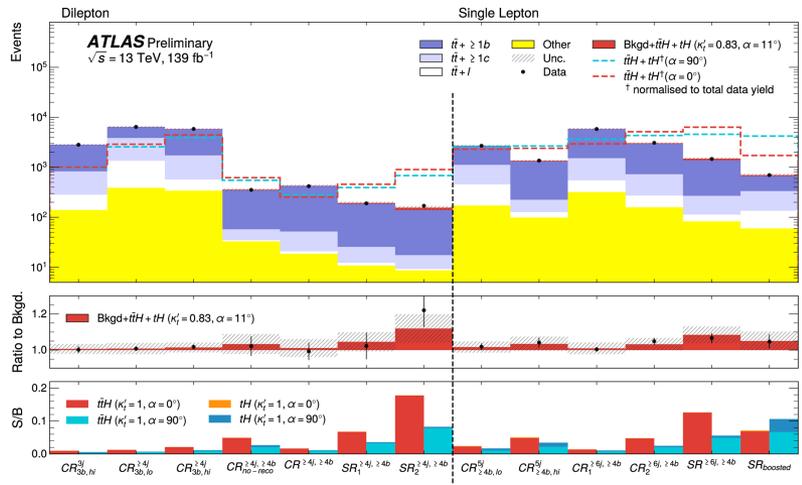

PSR: Preliminary Signal Region (before classification BDT)

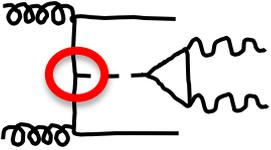

- Recent analysis with  $H \rightarrow bb$  decay
  - High branching ratio, but challenging backgrounds
  - Complementary to previous  $ttH(H \rightarrow \gamma\gamma)$  analysis
- Two channels:
  - Lepton+jets: target 1 semi-leptonic top decay – dedicated boosted region targets  $p_T^H > 200$  GeV using large-R jets ( $R=1, m_j > 50$  GeV)
  - Dilepton: target 2 semi-leptonic top decays
- Reconstruct top and Higgs candidates in regions
  - “Reconstruction” BDT selects jet combinations to build top and Higgs candidates
  - “Classification” BDT separates signal (trained on  $ttH$ ) from background

# H-top Coupling in ttH/tH production

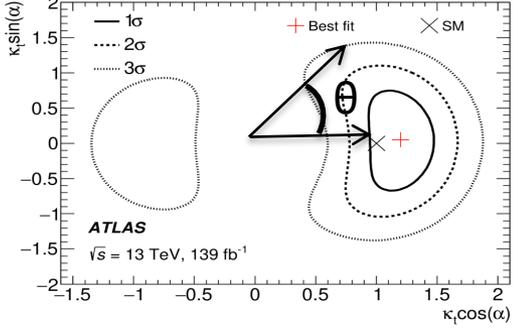

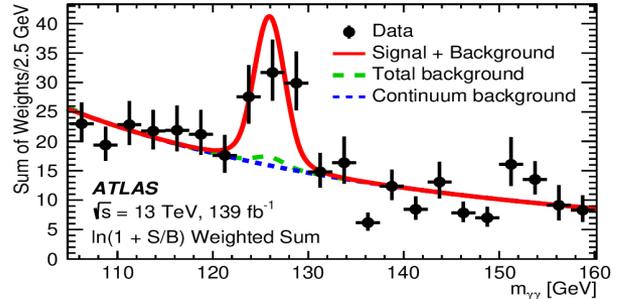

- Reconstruct Leptonic or Hadronic  $\gamma\gamma + \text{top}$  events
- Two BDTs to define 2D space:
  - Reject **continuum background** and
  - Enrich in **CP-odd-like** events (kinematic and angular variables)
- Simultaneous fit to  $m_{\gamma\gamma}$  in 2D regions defined by BDT outputs
  - Established  $5\sigma$  observation of **ttH( $\gamma\gamma$ )**
  - Assuming SM decay get  $\mu = 1.43^{+0.33}_{-0.31}(\text{stat})^{+0.17}_{-0.14}(\text{sys})$
  - Set upper limit of  $12\times\text{SM}$  for **tH** production
  - Pure **CP-odd** ( $\alpha = 90^\circ$ ) excluded at  $3.9\sigma$  and  $|\alpha| > 43^\circ$  at 95% C.L.
  - Statistics-dominated analysis

		← Hadronic Bkg Rejection BDT discriminant →					
Hadronic CP BDT discriminant ↑	Continuum background	<b>Rejected</b>			SM ttH/tH		
			12	9	6	3	
			11	8	7	5	2
			10		4	1	CP odd ttH/tH

$$\mathcal{L} = -\frac{m_t}{v} \{ \bar{\psi}_t \kappa_t [\cos(\alpha) + i \sin(\alpha) \gamma_5] \psi_t \} H$$

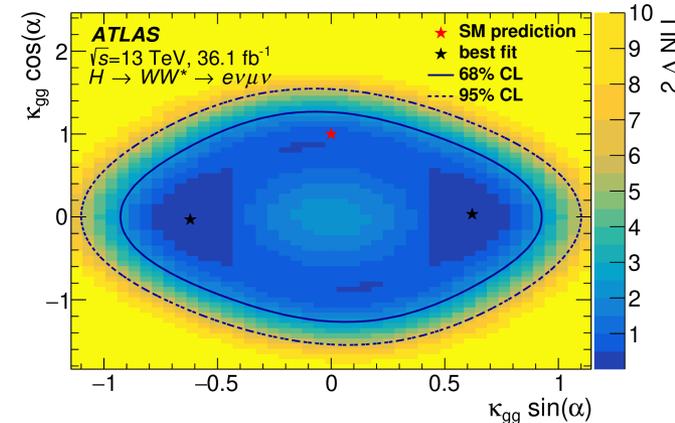

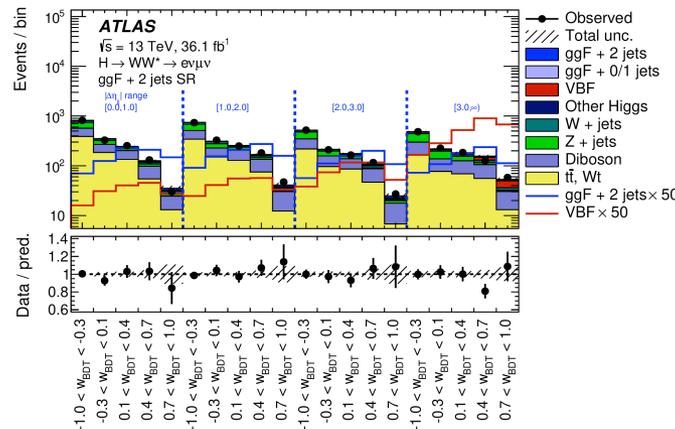

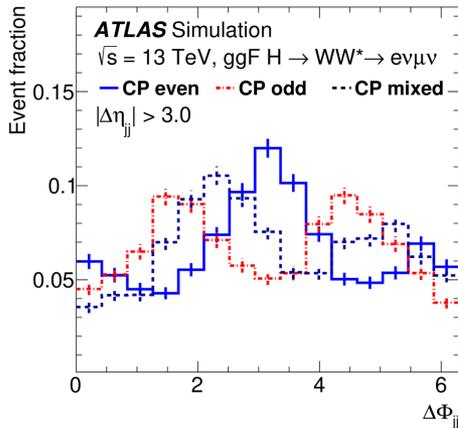

# Hgg Effective Coupling

- Depending on the production mode, H+2 jets probe CP violation (for ggF) or W/Z polarization (for VBF)
- In gluon fusion:
  - Effective vertex either or top Yukawa coupling or BSM particles in loop
  - Use BDT to separate signal and background (no CP sensitivity)
  - Classify H+2jets into 4x5 categories according to  $|\Delta\eta|$  and BDT score

$$\mathcal{L}_0^{\text{loop}} = -\frac{g_{Hgg}}{4} \left( \kappa_{gg} \cos(\alpha) G_{\mu\nu}^a G^{a,\mu\nu} + \kappa_{gg} \sin(\alpha) G_{\mu\nu}^a \tilde{G}^{a,\mu\nu} \right) H$$

$$\tan(\alpha) = 0.0 \pm 0.4(\text{stat.}) \pm 0.3(\text{syst.})$$

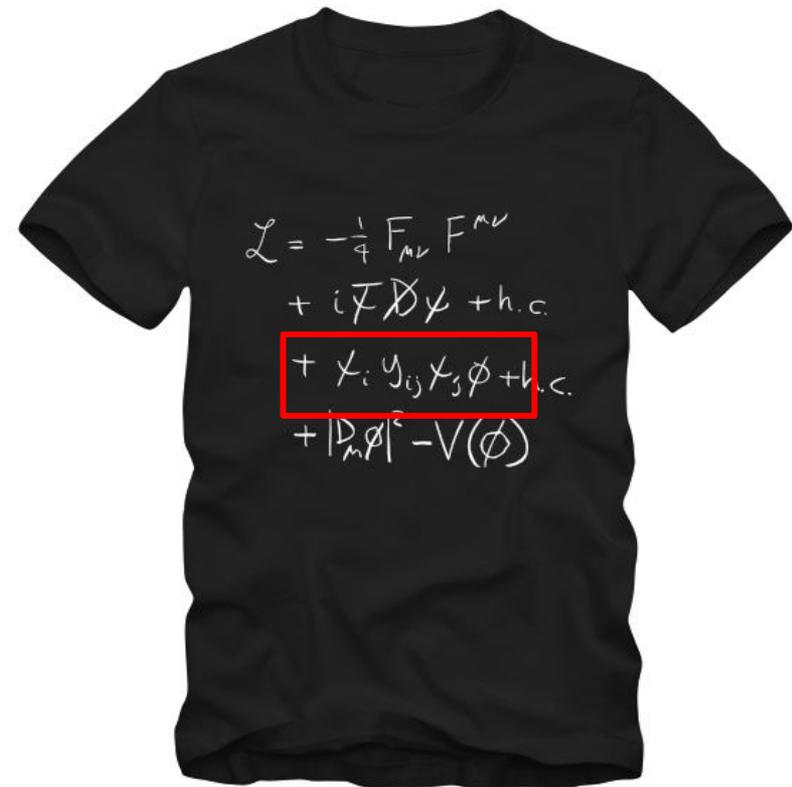

- Search for changed **shapes** of differential cross sections due to CP-odd observables (2<sup>nd</sup> term)
- Or on process **rates** (cross sections) from 3<sup>rd</sup> term – but other BSM scenarios can change rates

$$|\mathcal{M}|^2 = |\mathcal{M}_{\text{SM}}|^2 + 2 \cdot c_i \cdot \text{Re}(\mathcal{M}_{\text{SM}}^* \mathcal{M}_{\text{CP-odd}}) + c_i^2 \cdot |\mathcal{M}_{\text{CP-odd}}|^2.$$

See e.g. arXiv:2208.02338 [hep-ex], arXiv:1008.3869v3 [hep-ph], or C.Grefe, ICHEP'22

# Summary

- Higgs sector measurements look SM-like so far
- **But there is new physics out there!**
- Higgs is a unique particle at the center of the Standard Model edifice
- It is the only fundamental scalar and connected to electroweak symmetry breaking
- A great window to look beyond the Standard Model
- And we have only collected  $\approx 150 \text{ fb}^{-1}$  of  $3000 \text{ fb}^{-1}$  of 13 TeV data expected at the HL-LHC

T H E T R U T H I S O U T T H E R E .

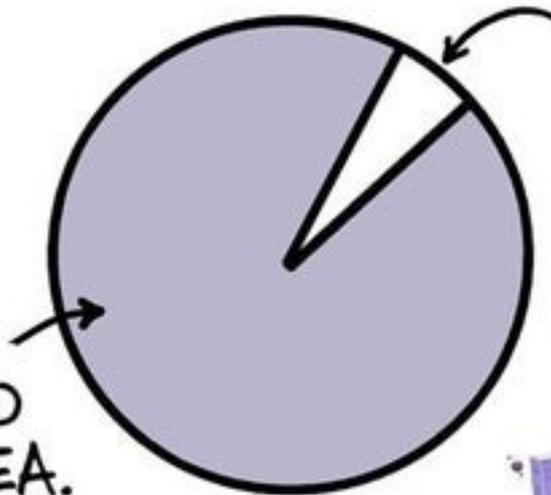

**STAY TUNED!**

THE TRUTH IS OUT THERE.

*Want to believe*

# THE UNIVERSE AS WE KNOW IT:

WE HAVE NO  
FREAKING IDEA.

EVERYTHING WE  
KNOW, EVERYTHING  
WE SEE, ALL THE  
ATOMS IN YOUR BODY  
AND IN OUR GALAXY,  
ALL THE STARS AND  
DUST AND PLANETS  
WITHIN AND OUTSIDE  
OF OUR SOLAR  
SYSTEM.
