Part I

Why a new fixed-target experiment for HEP now ?

J.P. Lansberg (IPNO, Paris-Sud U.)

A Fixed Target ExpeRiment at the LHC

September 6, 2013 3 / 40

Decisive advantages of Fixed-target experiments

• Fixed-target experiments offer specific **advantages** that are still nowadays **difficult to challenge by collider experiments**

Decisive advantages of Fixed-target experiments

- Fixed-target experiments offer specific **advantages** that are still nowadays **difficult to challenge by collider experiments**
- They exhibit 4 decisive features,
 - accessing the high Feynman x_F domain ($x_F \equiv \frac{p_z}{p_{z_{max}}}$)
 - achieving high luminosities with dense targets,
 - varying the atomic mass of the target almost at will,
 - polarising the target.

E866 at Fermilab with the Tevatron beam

– **Precision** Υ studies in *pp* and *pd* collisions

E866 PRL 100 (2008) 062301

Precision: necessary to show a different behaviour from DY

E866 at Fermilab with the Tevatron beam

– Precision Υ studies in *pp* and *pd* collisions

E866 PRL 100 (2008) 062301

Precision: necessary to show a different behaviour from DY

- Precision J/ψ and $\psi(2S)$ studies in pA collisions E866 PRL 84 (2000) 3256

Precision: necessary to show a different behaviour of $\psi(2S)$ vs. J/ψ

J.P. Lansberg (IPNO, Paris-Sud U.)

• The channeling efficiency is high for a deflection of a few mrad

J.P. Lansberg (IPNO, Paris-Sud U.) A Fixed Target ExpeRiment at the LHC

•

The channeling efficiency is high for a deflection of a few mrad
 One can extract a significant part of the beam loss (10⁹p⁺s⁻¹)

The Sec. 74

14/40

4 A N

- The channeling efficiency is high for a deflection of a few mrad
- One can extract a significant part of the beam loss $(10^9 p^+ s^{-1})$
- Simple and robust way to extract the most energetic beam ever:

J.P. Lansberg (IPNO, Paris-Sud U.)

A Fixed Target ExpeRiment at the LHC

The beam extraction: news

[S. Montesano, Physics at AFTER using LHC beams, ECT* Trento, Feb. 2013] Goal : assess the possibility to use bent crystals as primary collimators in hadronic accelerators and colliders

UA9 installation in the SPS

Prototype crystal collimation system at SPS :

- local beam loss reduction (5÷20x reduction for proton beam)
- beam loss map show average loss reduction in the entire SPS ring
- halo extraction efficiency 70÷80% for protons (50÷70% for Pb)

The beam extraction: news

[S. Montesano, Physics at AFTER using LHC beams, ECT* Trento, Feb. 2013] Goal : assess the possibility to use bent crystals as primary collimators in hadronic accelerators and colliders

LUA9 future installation in LHC

Prototype crystal collimation system at SPS :

- local beam loss reduction (5÷20x reduction for proton beam)
- beam loss map show average loss reduction in the entire SPS ring
- halo extraction efficiency 70÷80% for protons (50÷70% for Pb)

The beam extraction: news

[S. Montesano, Physics at AFTER using LHC beams, ECT* Trento, Feb. 2013] Goal : assess the possibility to use bent crystals as primary collimators in hadronic accelerators and colliders

LUA9 future installation in LHC

Prototype crystal collimation system at SPS :

- local beam loss reduction (5+20x reduction for proton beam)
- beam loss map show average loss reduction in the entire SPS ring
- halo extraction efficiency 70÷80% for protons (50÷70% for Pb)

Towards an installation in the LHC : propose and install during LSI a min. number of devices

• 2 crystals

Long term plan is ambitious : propose a collimation system based on bent crystals for the upgrade of the current LHC collimation system

• Expected proton flux $\Phi_{beam} = 5 \times 10^8 \ p^+ s^{-1}$

- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
 - the crystal sees $2808 \times 11000 \; s^{-1} \simeq 3.10^7$ bunches s^{-1}
 - one extracts $5.10^8/3.10^7 \simeq 15p^+$ from each bunch at each pass
 - Provided that the probability of interaction with the target is below 5%,
- Extraction over a 10h fill:
 - $5 \times 10^8 p^+ \times 3600 \text{ s } \text{h}^{-1} \times 10 \text{ h} = 1.8 \times 10^{13} p^+ \text{ fill}^{-1}$
 - This means $1.8 \times 10^{13}/3.2 \times 10^{14} \simeq 5.6\%$ of the p^+ in the beam

These protons are lost anyway !

no pile-up !

A few figures on the (extracted) proton beam

- Beam loss: 10⁹ p⁺s⁻¹
- Extracted intensity: $5 \times 10^8 \ p^+ s^{-1}$ (1/2 the beam loss) E. Uggerhei, UJ Uggerhei, NIM B 234 (2005) 31
- Number of p^+ : 2808 bunches of $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
 - the crystal sees $2808 \times 11000 \; s^{-1} \simeq 3.10^7$ bunches s^{-1}
 - one extracts $5.10^8/3.10^7 \simeq 15p^+$ from each bunch at each pass
 - Provided that the probability of interaction with the target is below 5%,
- Extraction over a 10h fill:
 - $5 \times 10^8 p^+ \times 3600 \text{ s} \text{ h}^{-1} \times 10 \text{ h} = 1.8 \times 10^{13} p^+ \text{ fill}^{-1}$
 - This means $1.8 \times 10^{13}/3.2 \times 10^{14} \simeq 5.6\%$ of the p^+ in the beam

These protons are lost anyway !

similar figures for the Pb-beam extraction

no pile-up !

LHB, a fixed target experiment at LHC to measure CP violation in B mesons

Flavio Costantini

University of Pisa and INFN, Italy

A fixed target experiment at LHC to measure CP violation in B mesons is presented. A description of the proposed apparatus is given together with its sensitivity on the CP violation asymmetry measurement for the two benchmark decay channels $B^0 \rightarrow J/\psi + K_s^0$, $B^0 \rightarrow \pi^+ \pi^-$. The possibility of obtaining an extracted LHC beam hinges on channeling in a bent silicon crystal. Recent results on beam extraction efficiencies measured at CERN SPS based on this technique are presented.

1. Introduction

•••

This paper presents a fixed target experiment to measure CP violation in the B system based on the possibility of extracting the 8 TeV LHC proton beam using a bent silicon crystal [4]. A 10% extraction efficiency of the LHC beam halo will give an extracted beam intensity of about 10⁸ protons/s allowing the production of as many as 10¹⁰ BB pairs per year, i.e. about two orders of magnitude more than what could be produced by an e⁺e⁻ asymmetric B factory with 10^{34} cm⁻³s⁻¹ luminosity [5].

- For LHCb, typically 1 fb⁻¹ means $\simeq 2 \times 10^{11} B\overline{B}$ pairs at 14 TeV
- LHB turned down in favour of LHCb mainly because of the fear of a premature degradation of the bent crystal due to radiation damages.
- $\bullet\,$ Nowadays, degradation is known to be $\simeq 6\%$ per $10^{20}\,$ particles/cm^2
- 10²⁰ particles/cm² : one year of operation for realistic conditions
- After a year, one simply moves the crystal by less than one mm ...

Simone Montesano - February 11th, 2013 - Physics at AFTER using the LHC beams

Crystal resistance to irradiation

- IHEP U-70 (Biryukov et al, NIMB 234, 23-30):
 - 70 GeV protons, 50 ms spills of 10¹⁴ protons every 9.6 s. several minutes irradiation
 - equivalent to 2 nominal LHC bunches for 500 turns every 10 s
 - 5 mm silicon crystal, channeling efficiency unchanged
- SPS North Area NA48 (Biino et al, CERN-SL-96-30-EA):
 - 450 GeV protons, 2.4 s spill of 5 x 10¹² protons every 14.4 s, one year irradiation, 2.4 x 1020 protons/cm2 in total,
 - · equivalent to several year of operation for a primary collimator in LHC
 - 10 x 50 x 0.9 mm³ silicon crystal, 0.8 x 0.3 mm² area irradiated, channeling efficiency reduced by 30%.
- HRMT16-UA9CRY (HiRadMat facility, November 2012):
 - 440 GeV protons, up to 288 bunches in 7.2 us, 1.1 x 10¹¹ protons per bunch (3 x 10¹³ protons in total)
 - · energy deposition comparable to an asynchronous beam dump in LHC
 - · 3 mm long silicon crystal, no damage to the crystal after accurate visual inspection, more tests planned to assess possible crystal lattice damage
 - accurate FLUKA simulation of energy deposition and residual dose

S. Montesano (CERN - EN/STI) @ ECT* Trento workshop. Physics at AFTER using the LHC beams (Feb. 2013)

э

• Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments

A B F A B F

 Both p and Pb LHC beams can be extracted without disturbing the other experiments • Extracting a few per cent of the beam $\rightarrow 5 \times 10^8$ protons per sec

J.P. Lansberg (IPNO, Paris-Sud U.)

E N 4 E N

- Both p and Pb LHC beams can be extracted without disturbing the other experiments
 Extraction a few per cent of the beam of Ex 10⁸ pretons per cent
- Extracting a few per cent of the beam $\rightarrow 5 \times 10^8$ protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at $\sqrt{s} = 115 \text{ GeV}$ and $\sqrt{s_{NN}} = 72 \text{ GeV}$

E N 4 E N

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam $\rightarrow 5 \times 10^8$ protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at $\sqrt{s} = 115 \text{ GeV}$ and $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of

BA 4 BA

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam $\rightarrow 5 \times 10^8$ protons per sec
- This allows for high luminosity pp, pA and PbA collisions at $\sqrt{s} = 115 \text{ GeV}$ and $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of
 - high luminosity (reach in y, P_T , small BR channels)
 - target versatility (nuclear effects, strongly limited at colliders)
 - modern detection techniques (e.g. γ detection with high multiplicity)

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam $\rightarrow 5 \times 10^8$ protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at $\sqrt{s} = 115 \text{ GeV}$ and $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of
 - high luminosity (reach in y, P_T , small BR channels)
 - target versatility (nuclear effects, strongly limited at colliders)
 - modern detection techniques (e.g. γ detection with high multiplicity)
- This would likely prepare the ground for $g(x, Q^2)$ extraction

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments

Beam extraction

• Beam extraction @ LHC

... there are extremely promising possibilities to extract 7 TeV protons from the circulating beam by means of a bent crystal.

... The idea is to put a bent, single crystal of either Si or Ge (W would perform slightly better but needs substantial improvements in crystal quality) at a distance of $\simeq 7\sigma$ to the beam where it can intercept and deflect part of the beam halo by an angle similar to the one the foreseen dump kicking system will apply to the circulating beam.

... ions with the same momentum per charge as protons are deflected in a crystal with similar efficiencies

If the crystal is positioned at the kicking section, the whole dump system can be used for slow extraction of parts of the beam halo, the particles that are anyway lost subsequently at collimators.

R. G. Roberts Rutherford Appleton Laboratory, Didcot, Oxon, England

W. J. Stirling

Department of Physics, University of Durham, Durham, England (Received 27 July 1987)

We perform a next-to-leading-order structure-function analysis of deep-inelastic μN and νN scattering data and find acceptable fits for a range of input gluon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1) "soft," (2)"-hard(") and (3) which behave as $\sigma(X) - 1/\sqrt{x}$ at small x. J/ψ and promph hoton hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon ditribution, is favored. M', Z_{in} and ig production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for σ_{μ} directly measured at DESY HERA.

We perform a next-to-leading-order structure-function analysis of deep-inelastic μN and νN scattering data and find acceptable fits for a range of input gloon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1) $\nu s(r)$, (2) $\mu range (2)$ and (3) which behave as $\sigma(X) - 1/\sqrt{x}$ at small x. J_{ν}^{A} and prompt photon hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon distribution, is favored. W_{ν}^{Z} and give production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for σ_{μ} directly measured at DESY HERA.

• Production $puzzle \rightarrow quarkonium$ not used anymore in global fits

Structure-function analysis and ψ , jet, W, and Z production: Determining the gluon distribution

> A. D. Martin Department of Physics, University of Durham, Durham, England

R. G. Roberts Rutherford Appleton Laboratory, Didcot, Oxon, England

W. J. Stirling Department of Physics, University of Durham, Durham, England (Received 27 July 1987)

We perform a next-to-leading-order structure-function analysis of deep-inelastic μN and νN scattering data and find acceptable fits for a range of input gluon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1) $\nu s(h, '2)$ $h^2 dn' and (3) which behaves as <math>\sigma(X) - 1/\sqrt{x}$ at small x. J/ϕ and promph hoton hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon distribution, is favored. W, Z, and gir production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for σu directly measured to Dilder measurements to yield information on the number of light neutrinos and the mass of the top quark. Finally we discuss how the gluon distribution at very small x may be directly measured at DESY HERA.

Production puzzle → quarkonium not used anymore in global fits
With systematic studies, one would restore its status as gluon probe

J.P. Lansberg (IPNO, Paris-Sud U.)

The same picture also holds for open heavy flavour

Observation of J/ψ sequential suppression seems to be hindered by • the Cold Nuclear Matter effects: non trivial and

... not well understood

Observation of J/ψ sequential suppression seems to be hindered by

• the Cold Nuclear Matter effects: non trivial and

... not well understood

- the difficulty to observe directly the excited states which would melt before the ground states
 - χ_c never studied in AA collisions
 - ψ(2S) not yet studied in AA collisions at RHIC

Observation of J/ψ sequential suppression seems to be hindered by

• the Cold Nuclear Matter effects: non trivial and

... not well understood

- the difficulty to observe directly the excited states which would melt before the ground states
 - χ_c never studied in AA collisions
 - ψ(2S) not yet studied in AA collisions at RHIC
- the possibilities for *cc* recombination
 - Open charm studies are difficult where recombination matters most

i.e. at low P_T

• Only indirect indications –from the y and P_T dependence of R_{AA}–

that recombination may be at work

• CNM effects may show a non-trivial y and P_T dependence ...
